Notes:

1. Due to high rock content, there was only sufficient material to do a sieve analysis and hydrometer test for SJSC-C; hydraulic conductivity and x-ray diffraction test were not performed
2. SJSC-A, SJSC-B, SCRWA-A, DI-A, DI-B did not have sufficient effluent data to estimate hydraulic conductivity
3. Mineral legend: C = Chlorite, F = Feldspar, HIM = Hydroxy-Interlayered 2:1 Mineral, K = Kaolinite, M = Mica, Q = Quartz, S = Smectite, V = Vermiculite
4. Observed Hydraulic Conductivity dervived from Darcy's Law, K = Q / iA, i is taken as 1 ft/ft
5. N/A - Not applicable.
6. SJSC-D and SCRWA-D are samples with gypsum added.
7. USCS - Unified Soil Classification System
8. Quartz, feldspar, and hydryoxy-interlayer 2:1 mineral are not clay mineral but were observed in testing.

TABLE II-3-3: SJSC-A (fine-grained)
ANALYTICAL DATA
BENCH SCALE TEST
RECYCLED WATER STUDY

	Sample ID	SJ/SC WPCP Source Influent				Soil Core SJSC-A Effluent		% Rem
	Round	1st	1st (Dup)	2nd	2nd (Dup)	1st	2nd	1st
Parameter	Units							
Analytical Method: handheld instrument								
Dissolved Oxygen (DO)	mg/L	0.04	0.04	8.1	8.6	8.4	NA	-20900.0%
ORP	mV	417	417	244	221	160	NA	61.6%
pH		7.4	7.4	7.3	8.0	7.6	NA	-2.7%
Residual Chlorine	mg/L	8.8	8.8	0.0	0.0	0.0	NA	100.0%

Notes:

Dup - denotes a field duplicate sample. A percent difference above 25% is indicative of a significant difference.

NA - denotes not available. For effluent results, this indicates there was inadequate volume to collect a sample. For % Rem, this indicates the value could not be calculated.

% Rem - is the percent concentration removal from influent to effluent of the given round and can be expresed as [(influent - effluent) / inluent]. Non detected values are treated at the reporting limit. A positive value is indicative of removal.

All constituents that could be analayzed are listed in Table II-3-1. In some cases, there was not enough volume to analyze for all the constituents in Table II-3-1.

Locus
TECHNOLOGIES

Notes:

ND - denotes result was below the detection limit
NT - dentoes sample was not tested
Dup - denotes a field duplicate sample. A percent difference above 25% is indicative of a significant difference.
NA - denotes not available. For effluent results, this indicates there was inadequate volume to collect a sample. For % Rem, this indicates the value could not be calculated.
% Rem - is the percent concentration removal from influent to effluent of the given round and can be expresed as [(influent - effluent) / inluent]. Non detected values are treated at the reporting limit. A positive value is indicative of removal.
Nitrate and Nitrite not tested in the core effluent secound round because hold time of sample would have been significantly exceeded
All constituents that could be analayzed are listed in Table II-3-1. In some cases, there was not enough volume to analyze for all the constituents in Table II-3-1.

Flags:

C - The sample was analyzed beyond holding time
Q5 - Sample received with inadequate chemcial perservation, but perserved by the laboratory.
O-04 - This analysis was performed outside the EPA recommended holding time.
O-09 - This sample was received with the EPA recommended holding time expired.

Notes:

ND - denotes result was below the detection limit

NT - dentoes sample was not tested

Dup - denotes a field duplicate sample. A percent difference above 25% is indicative of a significant difference.

NA - denotes not available. For effluent results, this indicates there was inadequate volume to collect a sample. For % Rem, this indicates the value could not be calculated.

% Rem - is the percent concentration removal from influent to effluent of the given round and can be expresed as [(influent - effluent) / inluent]. Non detected values are treated at the reporting limit. A positive value is indicative of removal.

Nitrate and Nitrite not tested in the core effluent secound round because hold time of sample would have been significantly exceeded

All constituents that could be analayzed are listed in Table II-3-1. In some cases, there was not enough volume to analyze for all the constituents in Table II-3-1.

Flags:

C - The sample was analyzed beyond holding time

Q5 - Sample received with inadequate chemcial perservation, but perserved by the laboratory.

O-04 - This analysis was performed outside the EPA recommended holding time.

O-09 - This sample was received with the EPA recommended holding time expired.

Notes:

ND - denotes result was below the detection limit

NT - dentoes sample was not tested

NA - denotes not available. For effluent results, this indicates there was inadequate volume to collect a sample. For % Rem, this indicates the value could not be calculated.

% Rem - is the percent concentration removal from influent to effluent of the given round and can be expresed as [(influent - effluent) / inluent]. Non detected values are treated at the reporting limit. A positive value is indicative of removal.

All constituents that could be analayzed are listed in Table II-3-1. In some cases, there was not enough volume to analyze for all the constituents in Table II-3-1.

Flags:

C - The sample was analyzed beyond holding time

O-04 - This analysis was performed outside the EPA recommended holding time.

O-09 - This sample was received with the EPA recommended holding time expired.

M2 - Matrix spike reovery was low; the associated blank spike recovery was acceptable

L3 - The associated blank spike recovered was above method acceptance limits

Notes:

ND - denotes result was below the detection limit

NT - dentoes sample was not tested

NA - denotes not available. For effluent results, this indicates there was inadequate volume to collect a sample. For % Rem, this indicates the value could not be calculated.

% Rem - is the percent concentration removal from influent to effluent of the given round and can be expresed as [(influent - effluent) / inluent]. Non detected values are treated at the reporting limit. A positive value is indicative of removal.

Nitrate and Nitrite not tested in the core effluent secound round because hold time of sample would have been significantly exceeded

All constituents that could be analayzed are listed in Table II-3-1. In some cases, there was not enough volume to analyze for all the constituents in Table II-3-1.

Flags:

C - The sample was analyzed beyond holding time

O-09 - This sample was received with the EPA recommended holding time expired.

M2 - Matrix spike reovery was low; the associated blank spike recovery was acceptable

L3 - The associated blank spike recovered was above method acceptance limits

Notes:

ND - denotes result was below the detection limit
NT - dentoes sample was not tested
NA - denotes not available. For effluent results, this indicates there was inadequate volume to collect a sample. For % Rem, this indicates the value could not be calculated.
% Rem - is the percent concentration removal from influent to effluent of the given round and can be expresed as [(influent - effluent) / inluent]. Non detected values are treated at the reporting limit. A positive value is indicative of removal.
Nitrate and Nitrite not tested in the core effluent secound round because hold time of sample would have been significantly exceeded
All constituents that could be analayzed are listed in Table II-3-1. In some cases, there was not enough volume to analyze for all the constituents in Table II-3-1.

Flags:

C - The sample was analyzed beyond holding time
O-09 - This sample was received with the EPA recommended holding time expired.
M2 - Matrix spike reovery was low; the associated blank spike recovery was acceptable
L3 - The associated blank spike recovered was above method acceptance limits

Total Coliform	MPN/100mL	Absent	Absent	238	2419	NA	NA

Notes:

ND - denotes result was below the detection limit

NT - dentoes sample was not tested

NA - denotes not available. For effluent results, this indicates there was inadequate volume to collect a sample. For % Rem, this indicates the value could not be calculated.

% Rem - is the percent concentration removal from influent to effluent of the given round and can be expresed as [(influent - effluent) / inluent]. Non detected values are treated at the reporting limit. A positive value is indicative of removal.

Nitrate and Nitrite not tested in the core effluent secound round because hold time of sample would have been significantly exceeded

PFCs not tested in the DI influent sample in the first round because sample was lost in transit to laboratory

All constituents that could be analayzed are listed in Table II-3-1. In some cases, there was not enough volume to analyze for all the constituents in Table II-3-1.

Flags:

C - The sample was analyzed beyond holding time

O-09 - This sample was received with the EPA recommended holding time expired.

L3 - The associated blank spike recovered was above method acceptance limits

TABLE II-3-12
SODIUM ADSORPTION RATIO

		Influent				Effluent				
		Calcium	Sodium	Magnesium		Calcium	Sodium	Magnesium

SCRWA-D	Second	54	160	32	4.3	55	140	31	3.7	-12.2
DI-C	First	ND 0.10	ND 0.50	ND 0.10	N/A	64	140	34	3.5	N/A
DI-C	Second	ND 0.10	ND 0.50	ND 0.10	N/A	150	14	40	0.3	N/A

Notes:

A positive change in SAR indicates an exchange of sodium ions for calcium and magnesium ions in the soil matrix which results in clay shrinkage (increased hydraulic conductivity).

A negative change in SAR indicates an exchange of calcium and magnesium ions for sodium ions in the soil matrix which results in clay expansion (reduced hydraulic conductivity).

THMs	Trihalomethanes
TOC	total organic carbon
TDS	total dissolved solids
µg/L	micrograms per liter
USCS	Unified soil classification system
VOC	Volatile organic carbon

EXECUTIVE SUMMARY

Volume III covers the third phase of the Recycled Water Irrigation and Groundwater Study. The overall goal of the study is to evaluate the potential impact to groundwater from expanded use of recycled water for irrigation in the Santa Clara and Llagas Subbasins. The scope of this volume is a pilot study of the potential impacts from irrigating with recycled water on vadose zone pore water and groundwater at a commercial facility in San Jose.

Description of Site and Monitoring Program

The pilot study was a full-scale test for observing the subsurface fate and transport of recycled water under real conditions for irrigation. The pilot study was conducted at the Integrated Device Technology (IDT) site located at 6024 Silver Creek Valley Road, San Jose, California (Figure III-2-1). The focus of the study is to determine if any constituents found in recycled water could potentially have a negative impact on groundwater when recycled water is used as a water source for irrigation.

The monitoring program for the pilot study included eight lysimeters and four exisitng monitoring wells. The four monitoring wells were used to monitor groundwater constituent concentrations in the shallowest saturated zone, a depth of approximately 30 feet below ground surface (bgs). The eight lysimeters consisted of four installed at five feet depth and four installed at ten feet depth. These lysimeters monitor the pore water in the vadose zone. Due to the high volume requirement for sampling and limited volume capacity in each lysimeter, samples from the four 5-foot depth lysimeters were composited as L5-COMP and the samples from the four 10-foot depth lysimeters were composited as L10-COMP. Recycled water at the irrigation point was also monitored. The irrigated recycled water for this site was derived from the San Jose/Santa Clara Water Pollution Control Plant (SJ/SC WPCP). Recycled water use at the site was first implemented on September 4, 2008. Additives to the landscape included only fertilizer and grub control.

The monitoring program for the pilot study included baseline sampling of the water source and the monitoring wells and 8 subsequent sampling events of the irrigation water, lysimeters and monitoring wells. The frequency of sampling events was initially set at 50 days apart and later adjusted to 75 days to account for slower-than-expected percolation rates and to obtain additional long-term monitoring data. Due to limited sample volume capacity in the lysimeters, interim sampling events were conducted to complete analyses that could not be completed within the regularly scheduled sampling event. The analytes monitored were based on findings from Volumes I and II of this report. A list of these constituents is shown in Table III-3-1.

Pilot Study Implementation

Irrigation of recycled water at the pilot study began on September 4, 2008. Sampling for the pilot study was performed between October 27, 2008 and March 15, 2010. An additional monitoring event occurred on May 19, 2008 prior to recycled water irrigation, which served as the baseline. Results from the data analysis presented in Volume I and previous monitoring by SCVWD on December 12, August 16, and May 16-17 of 2007 were used as supplemental baseline data for comparative purposes. Chemical results for all sampling events are found in Table III-4-1. In addition, charts graphically displaying the chemical results are provided in Figures III-4-1 through III-4-48.

Pilot Study Results

Irrigation of recycled water was implemented on a seasonal basis during periods when there was insufficient natural rainfall to irrigate the landscaping (Figure III-2-2). Over the study period, L5-COMP, which is nearest to the surface, did not exhibit patterns strongly reflective of seasonal changes with irrigation use.

Based on the results obtained from the pilot study, the constituents that showed the highest potential to impact groundwater were NDMA, HAA6, and PFCs, due to their appearance in groundwater during the pilot study. NDMA, HAA6, and PFCs were not detected in the groundwater at the IDT site in the baseline sampling events prior to use of recycled water. For the first two sampling events after recycled water use began at the site, NDMA concentrations were found in the pore water at or above the California Department of Public Health's drinking water notification level of 10 ng/L (CDPH, 2007). NDMA concentrations in the pore water in the third and subsequent events were below 10 ng/L.

PFCs have shown removal in recycled water through the vadose zone in the pilot study but have also appeared in the groundwater at the IDT site. PFBA in particular was not found in the recycled water but was found in pore water sample locations suggesting the transformation to PFBA from other products. HAA6 is also a concern because of its presence in the pore water and potential to reach groundwater.

Sodium, magnesium, and calcium are constituents in recycled water that may limit soil drainage through clay swelling. Findings in the pilot study suggest that clays were already expanded to some degree in the first five feet through the pilot study period. The change in permeability due to the clay swelling could not be quantitatively measured, but was observed to be significant in the bench test portion of the study as reported in Volume II. Soil drainage can be restricted when switching to a water source with a greater sodium adsorption ratio (SAR). In this case the SAR of the recycled water would have to be greater than that of the water source previously used for expansion to occur.

Constituents that indicated moderate potential to impact groundwater include TDS, boron, sulfate, chloride and pathogens. Rising concentrations of chloride in the pore water and groundwater at the IDT site during the pilot study present a concern for potential long-term impact. Overall, chloride removal in the bench test was not well observed. Some biological constituents, specifically heterotrophic bacteria and total coliforms, were found to be present in the recycled water and to some extent in the pore water and groundwater. Overall there is some evidence from the pilot study suggesting that pathogens in recycled water could potentially impact groundwater. TDS results in groundwater, pore water, and recycled water from the pilot study including baseline data exceeded secondary drinking water standards. Moderately high levels of TDS found in groundwater at the IDT site, as seen in the baseline and pilot study, leave less capacity for further increases in TDS due to incoming recycled water used in irrigation. Boron and sulfate data from the pilot study and bench test suggested that attenuation was low. The soil and fertilizer were suspected to contribute more sulfate in the pore water than recycled water alone.

Most constituents indicated only minimal potential to impact groundwater, including phosphate, nitrate, nitrite, potassium, TOC, DOC, and THMs. Major nutrients such as phosphate and nitrate/nitrite appear to be greatly reduced from irrigation when vegetation is present and fertilizer is not overused. The plant uptake process is believed to be the major pathway for nutrient removal. TOC and DOC were not observed to reach groundwater in the pilot study.

Potassium and THMs were relatively stable in the groundwater through the pilot study. THMs were not detected in groundwater. Potassium was detected in groundwater but at concentrations similar to baseline levels. In addition, bench test data of potassium and THMs generally exhibited removal in the soil.

Alkalinity, pH, ORP, DO, and total chlorine showed negligible potential to impact groundwater through recycled water use. The stability of general parameters (pH, ORP and DO) as seen in the pilot study and bench test indicates that there were no major shifts in conditions in the vadose zone. Chlorine measurements in the pilot study in groundwater were generally higher than in recycled water.

VOCs (excluding THMs) were not detected consistently in recycled water in either the bench test or the pilot study and did not pose a potential threat to groundwater at the IDT site. In addition, Volume I of this study found that xylenes and carbon tetrachloride were regarded as having D) minimal potential impact. The data analysis of Volume I also did not find detections of any other VOCs in recycled water.

Cyanide, terbuthylazine, NTA, and perchlorate were not detected consistently in recycled water in either the bench test or the pilot study. Detections that did occur were near or at the reporting limit. In groundwater, only perchlorate was detected once. Because these parameters were not frequently present in the recycled water source at IDT, they did not have impacts to the groundwater at the IDT site. However, the attenuation behavior of these constituents could not be well examined.

EDTA and surfactants were not consistently detected in the recycled water in the pilot study, thus conclusions from the pilot study could not be made. However, EDTA and surfactants were detected in the recycled water during the bench test and were found to not attenuate well in the bench test.

With respect to permeability and the SAR, sodium, calcium, and magnesium do have an impact on groundwater. The water composition, as indicated by the SAR, from the recycled water and the pore water five feet bgs is more sodium-concentrated than the pore water from ten feet bgs and the groundwater. SAR data suggest the presence of clay swelling in the first five feet. However, the impact of the clay swelling on soil permeability could not be quantitatively measured. The sodium, calcium, and magnesium in the pore water at five feet bgs indicates the soil near the surface was already saturated with these three constituents, likely as a result of previous irrigation. Based on these findings, permeability changes due to recycled water as an irrigation source in clay type soils could present a concern for soil drainage when the SAR in recycled water is greater than the previous irrigation source.

Trends for the pilot study were determined in several ways including a piper diagram analysis and Mann-Kendall analysis. The piper diagram analysis used the cation and anion data to evaluate the trends in the groundwater and in the lysimeters. This approach evaluated the cations (calcium, magnesium, sodium, and potassium), and anions (chloride, sulfate, and bicarbonate) on the percent composition based on equivalence per volume concentrations. Results of the piper diagram analysis indicate a shift in the pore water and groundwater towards an ionic composition similar to that of recycled water. This is most evident in L5-COMP which is at the shallowest depth; however this trend is also discerned in the groundwater. The Mann-Kendall analysis was another approach used to evaluate trends. The Mann-Kendall analysis is a nonparametric statistical test used to to assess trends over time. The Mann-Kendall trends were evaluated for each constituent and location over time.

Below is a table summarizing the potential threat to groundwater with respect to each constituent based on findings from the pilot study and bench test. Each constituent is given a rating between 1 and 5, with 5 representing the highest potential threat. The criteria for assigning each threat are the observed attenuation of the constituent in the pilot study and bench test and the type of constituent. In general, the greater the overall attenuation behavior displayed from the bench test and pilot study the lower the potential threat is. Also considered is whether the constituent is naturally occurring or has known health impacts. The type of constituent can range from general water quality parameters like alkalinity and DO, to emerging contaminants like NDMA and PFCs. The potential threat assigned for each constituent below is a culmination of these factors. Some monitored constituents were not consistently detected in the recycled water source during the study. Since the attenuation of those constituents could not be evaluated, they are assigned as inconclusive. Further monitoring of recycled water sources is needed to determine whether those constituents are sufficiently present to pose a potential threat to groundwater.

In addition to the potential threat value, the table includes a recommendation on whether further monitoring of each constituent is warranted. Constituents that are recommended for further monitoring are those with a threat value of three or higher. The evaluation of potential threats presented below is based on the 18-month pilot study conducted at the IDT site. Due to the fairly limited monitoring period for this study, it is possible that the arrival of some constituents did not occur within the pilot study duration. As part of an agreement with the SCVWD, IDT is conducting ongoing groundwater monitoring at the site, and those results should be considered along with the findings of this study to guide future efforts.

Constituent	**Potential Threat**	**Recommend for Further Monitoring?**	**Findings**
ORP	1	N	ORP is a general water quality parameter. Measurements of ORP suggest no major shifts in redox conditions.
pH	1	N	The pH is a general water quality parameter. The pH was near neutral in the pilot study and bench test. Similarity of pH across depth indicates conditions are stable.
Chlorine, Total	1	N	Concentrations of chlorine were higher in groundwater than in recycled water and pore water in the pilot study.
Dissolved Oxygen	1	N	DO is a general water quality parameter. DO was 0.01 mg/L or above across depth in the pilot study indicating that anoxic conditions are unlikely. Samples from the bench test indicated oxic conditions.
Alkalinity, Total	1	N	Alkalinity is a general water quality parameter. A greater alkalinity in the pore water equates to more stability in pH conditions.
Bicarbonate Alkalinity	1	N	
Boron	3	Y	Boron removal was not well observed in the bench test or pilot study.

Calcium	2	Y (See SAR)	Calcium concentrations are greater in the subsurface than in recycled water.
Magnesium	2	Y (See SAR)	Magnesium concentrations are greater in the subsurface than in recycled water.
Sodium	4	Y	Sodium is directly related to SAR, as well as having a direct potential effect on groundwater.
Sodium Adsorption Ratio (SAR)	4	Y	SAR may indicate impact to soil drainage from clay swelling as a result of recycled water application when the SAR in the recycled water is higher than the SAR of the previous irrigation source.
Potassium	1	N	Potassium data from bench test and pilot study suggest good removal.
Sulfate	3	Y	Sulfate increased in concentration in pore water, likely due to contribution from soil and fertilizer. Sulfate concentration in groundwater was relatively stable in the pilot study. In the bench test, removal was not well observed. The constituent also contributes to the total dissolved solids.
Nitrite	2	N	Nitrate/Nitrite data show removal with depth in the pilot study. Mechanism is suspected to be attenuation by root uptake pathway.
Nitrate	2	N	
Chloride	4	Y	Chloride over time has shown an increasing trend in concentrations in groundwater and pore water. At the end of the pilot study, chloride had not yet reached stable conditions. Attenuation of chloride in the bench test was not well observed. The constituent also contributes to the total dissolved solids.
Total Organic Carbon (TOC)	2	N	TOC was decreased by microbial activity and adsorption to soil; groundwater was relatively stable in pilot study. The bench test findings were consistent with the pilot study.
Total Filterable Residue at 180C (TDS)	3	Y	Although TDS in the pilot study in groundwater appeared relatively stable, levels have been observed above secondary drinking water standards in both the baseline and subsequent events. TDS in recycled water and lysimeters are also above secondary drinking water standards. In the bench test, attenuation was not well observed.
Dissolved Organic Carbon	2	N	DOC was decreased by microbial activity and adsorption to soil; groundwater was relatively stable in pilot study. The bench test findings were consistent with the pilot study.

Bromodichloromethane (THM)	2	N	Bromodichloromethane was removed in the vadose zone. Bromodichloromethane was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.
Bromoform (THM)	2	N	Bromoform was removed in the vadose zone. Bromoform was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.
Chloroform (THM)	2	N	Chloroform was removed in the vadose zone. Chloroform was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.
Dibromochloromethane (THM)	2	N	Dibromochloromethane was removed in the vadose zone. Dibromochloromethane was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.
Carbon Tetrachloride (VOC)	1	N	Carbon tetrachloride was not detected in recycled water in pilot study or bench test. The constituent was also categorized as having minimal potential impact in Volume I.
Xylenes, Total (VOC)	1	N	Xylenes were not detected in recycled water in pilot study or bench test. The constituent was also categorized as having minimal potential impact in Volume I.
Additional 8010-list VOCs	1	N	VOCs were not detected in recycled water in the pilot study or bench test. VOCs excluding xylenes and carbon tetrachloride were also not detected in the data analysis of Volume I.
Haloacetic Acids (HAA6): Bromochloroacetic Acid Dibromoacetic Acid Monobromoacetic Acid Monochloroacetic Acid Trichloroacetic Acid	4	Y	HAA6 were not observed in the baseline groundwater samples but were observed in the applied recycled water, pore water, and groundwater during the pilot study. In the bench test, HAA6 attenuation was not well observed. HAA6 are also anthropogenic compounds.
Heterotrophic Plate Count	3	Y	Growth was present in pore water and groundwater. Growth was also observed in the bench test. Attenuation was not observed.
Coliforms, Total	3	Y	Growth was present in pore water and groundwater. Growth was also observed in the bench test. Attenuation was not observed.
Fecal Coliforms	3	Y	Fecal Coliforms were not present in groundwater during the pilot study. In the bench test, fecal coliforms were not frequently detected. Attenuation was not well observed.

E. Coli	Inconclusive	Y	E. Coli was minimally detected in recycled water in the pilot study. In the bench test, E. coli was not frequently detected. Therefore the attenuation behavior could not be examined. The constituent may be present in the other recycled water sources in the study area.
N-Nitroso Dimethylamine (NDMA)	5	Y	NDMA was not observed in the baseline groundwater samples, but was observed in the applied recycled water, pore water, and groundwater during the pilot study. The majority of attenuation of NDMA could potentially be from volatilization in the vadose zone and biotransformation in the soil. In the bench test, NDMA attenuation was not consistently observed. NDMA is an emerging contaminant.
Perfluorochemicals	5	Y	PFCs were not observed in the baseline groundwater samples, but were observed in the applied recycled water, pore water, and groundwater during the pilot study. Similarly, in the bench test, some PFCs were observed in the effluent but not in the influent. There is potential for PFC formation from precursors. PFCs are emerging contaminants.
Phosphate	1	N	Phosphate removal was observed in the pilot study and bench test. Mechanisms that caused removal of phosphates are suspected to be the root uptake pathway and precipitation.
Ethylenediaminetetraacetic acid (EDTA)	3	Y	EDTA was not detected in recycled water in the pilot study. In the bench test attenuation was not consistently observed.
Surfactants (MBAS)	3	Y	Surfactants were minimally detected in recycled water in the pilot study. In the bench test attenuation was not consistently observed.
Bromide	2	Y	Removal of bromide in the vadose zone is low; however the degree of toxicity of bromide is low. Together with chloride, bromide can be a useful tracer for recycled water transport.
Nitrilotriacetic acid (NTA)	Inconclusive	Y	NTA was not detected in the pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.
Perchlorate	Inconclusive	Y	Perchlorate was not detected in recycled water during the pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.

Cyanide	Inconclusive	Y	Cyanide was minimally detected in pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.
Terbuthylazine	Inconclusive	Y	Terbuthylazine was minimally detected in recycled water in pilot study and bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.

VOLUME III
SAN JOSE PILOT STUDY
RECYCLED WATER STUDY

1. INTRODUCTION

This report was prepared by Locus Technologies (Locus) on behalf of the Santa Clara Valley Water District (SCVWD) for the Recycled Water Irrigation and Groundwater Study. Volume III covers the third phase of a study to evaluate the impacts from expanded use of recycled water for irrigation on groundwater resources in the Santa Clara and Llagas Groundwater Subbasins in Santa Clara County. This study uses a combination of approaches, including literature review, data analysis, a fate and transport evaluation, and a full pilot study at a site in the Santa Clara Groundwater Subbasin. The first and second phases of this study are reported in Volumes I and II respectively. This volume focuses on the pilot study portion of the evaluation, but includes support from findings from the first and second phases of this study.

1.1. Purpose

This volume of the report includes the results from the pilot study conducted at the Integrated Device Technology (IDT) site located at 6024 Silver Creek Valley Road, San Jose, California. The pilot study serves as a way to observe the transport of recycled water and the attenuation of its constituents from the surface to the groundwater under real-world conditions. For this report, attenuation is defined as the reduction in concentration of a constituent through the soil, through any process including but not exclusive to sorption, volatilization, transformation, or plant uptake. Constituent migration is operationally defined as the movement of constituents in the vadose zone and in groundwater. The pilot scale test is the final component of the fate and transport evaluation (the other components in the fate and transport evaluation included a literature review, data analysis, soil model, and bench test, presented in Volumes I and II of this report). The pilot study is conducted in a real environment that is irrigated with recycled water. The purpose of the study is to evaluate the recycled water fate and transport through the vadose zone and into the shallow saturated zone. Fate and transport is assessed by looking at depth-discrete chemical data in water as it migrates through the vadose zone and into the saturated zone. The following specific goal was identified for the pilot test:

- Examine the attenuation through soil for a list of constituents present in recycled water that may negatively impact groundwater as determined in Volume I and Volume II.

Recycled water commonly contains a number of constituents introduced through the original use of the water, or through the treatment processes that the water undergoes after use. The focus of the study is chemical constituents, including those of anthropogenic and nonanthropogenic origins. A few constituents of concern are biological. This study focuses on determining whether any of these constituents have the potential to negatively impact groundwater if recycled water is used for irrigation.

2. SITE BACKGROUND

The pilot study was conducted in the Santa Clara Subbasin at the IDT site, located at 6024 Silver Creek Valley Road, San Jose, California. It is bounded by Silver Creek Valley Road and Piercy Road. The IDT property maintains 6.2 acres of landscape: 2.8 acres of irrigated turf and 3.4 acres of irrigated shrub beds (ITAP, 2006). The property contains flat and sloping turf areas and narrow shrub beds which have mature drought tolerant shrubs, large trees, and groundcover. Southwest of the subject property beyond Piercy Road, lies Coyote Creek which runs northwestward toward the San Francisco Bay (USGS, 2011).

2.1. Irrigation

2.1.1. Irrigation System

The current irrigation system uses Hunter gear driven rotors, Toro gear driven rotors, and Toro four-, six-, and twelve-inch plastic pop-up spray heads. There are 127 irrigation control valves that are managed by four Sentar Rain Master Controllers. Between October 2008 and March 2010, about 10,000 hundred cubic feet (ccf) or approximately 23 acre-feet of recycled water for irrigation was applied. Significantly less irrigation was used during the winter months compared to summer months.

The typical root zone for water uptake in lawns and garden is 6 to 12 inches. For shrubs the typical root zone is 12 to 24 inches, and for trees the zone is 18 to 36 inches.

2.1.2. Recycled Source Water

The source of the irrigation water for the pilot study is recycled water supplied from the San Jose/Santa Clara Water Pollution Control Plant (SJ/SC WPCP) which services wastewater treatment to cities in the Santa Clara Subbasin including San Jose, Santa Clara, Milpitas, Campbell, Cupertino, Los Gatos, Saratoga, and Monte Sereno. SJ/SC WPCP wastewater is treated in a three step process (City of San Jose, date unspecified). Primary treatment takes place in large settling tanks removing 40 to 60 percent of the suspended solids and 23 to 35 percent of the biochemical oxygen demand. Secondary treatment includes aeration and secondary clarifiers. The final step is tertiary treatment involving filtration through filter beds and then chlorination for disinfection. Pollutants and solid wastes removed from the three treatment steps are directed to anaerobic digesters. Post tertiary treatment, the portion reserved for reclamation is directed to an effluent diversion facility where the water is dosed with additional chlorine and is directed through a 4310-foot diversion pipeline at the end of which recycled water is distributed (Zadeh, 2010). These additional measures help meet the regulatory chlorine contact time (CT) of 450 mg-min/L (Title 22 §60301.230(a)). CT achieved at the end of the diversion pipeline ranges typically from 1000 to 4000 mg-min/L. SJ/SC WPCP recycled water meets Title 22 regulations.

With the exception of the baseline sampling, the location of the recycled water source sample is at the IDT site on a fixture directly attached to the irrigation line. Initial baseline sampling of the source was collected directly from the SJ/SC WPCP because recycled water use at the IDT site had not yet been implemented. Starting with the first sampling event, the recycled water samples for the study were taken directly from the irrigation system onsite. Recycled water use at the site was implemented on September 4, 2008. The irrigation system is not used as frequently during the winter months when it rains. Figure III-2-2 shows the irrigation use and precipitation data over the study period.

2.2. Vadose Zone

2.2.1. Soil Composition

Previous soil sampling indicated that most of the vadose zone soil at the site is made up of silty clay of medium plasticity. The unified soil classification system (USCS) identifies this soil with the code CL (lean clay). During the installation of the four monitoring wells at the site in 2005, soils were logged to 45 feet bgs by MJO Earthscience Services as part of an environmental baseline report for the IDT site (Pacific Crest Engineering Inc., 2005). The intent of the baseline report was to be used as a reference for when IDT eventually closes the subject site. In all four borings, groundwater was encountered at depths from 30 to 33 feet and well screens were installed between 25 and 45 bgs. However, the upper 30 feet consisted entirely of silty clay. Other shallower soil borings (four to five feet in depth) were also logged at 25 other locations at the site by MJO Earthscience Services, and the shallow soil type was consistently silty clay across the site. In 2008, Locus collected an additional soil core to 30 feet at a fifth location, and logged silty clay for the entire depth. Soil boring logs for all of these locations are included in Appendix III-A. Based on these soil boring logs, the soil appears to be uniform through the vadose zone and across the site. Because the soil characteristics appear to be homogeneous throughout the site, no areas were identified to be more sensitive to recycled water application based on soil type.

2.2.2. Lysimeters

Pore water from the vadose zone is represented by samples from the lysimeters. Four locations were chosen to have lysimeters installed. Since the shallow soil types at the site are not significantly variable, the lysimeter locations were selected based on accessibility and maximum expected infiltration rate. Based on irrigation rates and surface grading, irrigation water can be expected to infiltrate more heavily in some areas. Lysimeters were installed on July 17 and 18, 2008. Sample locations for the IDT site are shown in Figure III-2-1.

Two lysimeters were installed at each location: one at five feet bgs and the second at ten feet bgs. Lysimeters placed at five feet bgs are screened at 4.7 to five feet bgs. Lysimeters placed ten feet bgs are screened at 9.7 to ten feet bgs. According to previous studies discussed in Volume I, the attenuation of constituents is expected to be highest in the first several feet of the soil profile.

The lysimeters consisted of 54-inch long dual-chamber stainless steel lysimeters provided by Soil Measurement Systems. Each lysimeter has an outer diameter of 2 inches and an extractable sample storage capacity of 1,500 milliliters (mL). Lysimeters use a vacuum mechanism to collect pore water from unsaturated soil. The upper chamber of the lysimeter is used for sample storage and is designed to prevent back flow.

2.2.2.1. Lysimeters L1-5 and L1-10

Lysimeters L1-5 and L1-10 are located on the east end of a bed of turf grass which is adjacent to the west side of the second larger IDT building. These lysimeters are located in the lower end of a sloping turf bed. Half of the run-off from the sloping turf bed is directed to the L1 location. The other half is directed to the opposing end of the sloped turf bed where the L2 lysimeters are located. The sloping conditions of the turf bed result in more irrigation water infiltrating at this location. Two lysimeters were installed at the L1 location: one at a depth of five feet (L1-5) and one at a depth of ten feet (L1-10).

2.2.2.2. Lysimeters L2-5 and L2-10

Lysimeter L2-5 and L2-10 are located on the west end of a bed of turf grass which is adjacent to the west side of the larger second IDT building. These lysimeters are located in the lower end of a sloping turf bed. Half of the run off from the sloping turf bed is directed to the L2 location. The other half is directed to the opposing end of the sloped turf bed where the L1 lysimeters are located. The sloping conditions of the turf bed results in more irrigation water infiltrating at this location. Two lysimeters were installed at the L2 location: one at a depth of five feet (L2-5) and one at a depth of ten feet (L2-10).

2.2.2.3. Lysimeters L3-5 and L3-10

Lysimeter L3-5 and L3-10 are located on the north end of the property, in a strip of turf bed near the front driveway entrance. The turf bed is banked along the Silver Creek Valley Road. In addition to turf, the bed is lined with mature trees. The L3 location is located close to groundwater monitoring well MW-3 so that pore water and groundwater can be monitored at approximately the same location. Two lysimeters were installed at the L3 location: one at a depth of five feet (L3-5) and one at a depth of ten feet (L3-10).

2.2.2.4. Lysimeters L4-5 and L4-10

Lysimeter L4-5 and L4-10 are located on turf at the south end of the main field. The main field is located on the west end of the IDT property. These lysimeters are located close to MW-4 so that pore water and groundwater can be monitored at approximately the same location. Two lysimeters were installed at the L4 location: one at a depth of five feet (L4-5) and one at a depth of ten feet (L4-10).

2.2.2.5. Lysimeter Composites

The required sample volume needed to analyze for the full recycled water constituent list was 8000 mL. However, due to the limited water volume capacity of the lysimeters, it was not possible to collect adequate sample volumes from each lysimeter. Therefore, composite samples were collected to provide the sample volume required to accurately analyze for the entire list of constituents of concern. L5-COMP is the composite of L1-5, L2-5, L3-5, and L4-5. L10-COMP is the composite of L1-10, L2-10, L3-10, and L4-10. The composites allow for evaluating results with respect to soil depth. Variation between lysimeter locations could not be evaluated using composite sampling; however this variation is expected to be low due to the homogeneity of soil and surface conditions at the IDT campus.

2.3. Groundwater

Shallow groundwater on site is located at approximately 30 ft bgs. Based on the water levels of the existing monitoring wells, the groundwater flow direction appears to be north-northeast. A previous environmental investigation determined that the groundwater flow was westward (Pacific Crest Engineering Inc., 2005). The hydraulic gradient of the shallow groundwater is estimated to be 0.001 ft/ft. Because of the low hydraulic gradient, the groundwater flow direction is expected to fluctuate considerably, which may explain the differences in the groundwater flow direction over time. Any local pumping may potentially induce changes from the natural flow direction.

2.3.1. Existing Monitoring Wells

Shallow groundwater is represented by water from existing monitoring wells. In 2005, four groundwater monitoring wells were installed by Exploration Geoservices, Inc. as part of an environmental baseline report for the IDT site (Pacific Crest Engineering Inc., 2005). The four existing monitoring wells were installed to provide baseline data for when IDT eventually closes the subject site. The groundwater monitoring wells MW-1, MW-2, MW-3, and MW-4 are shown in Figure III-2-1. Each of these monitoring wells has a casing diameter of 4 inches and is screened from 25 to 45 feet bgs. Appendix III-A includes the boring logs and wells diagrams for these monitoring wells. The monitoring wells are used to monitor groundwater quality constituent concentrations in the shallowest saturated zone. The average screen depth is 35 ft bgs.

2.4. Landscape Additives

IDT regularly applies fertilizer and grub control onto the landscape. One of three fertilizers is utilized depending on the season. The three fertilizers used are Andersons Golf Products Turf Fertilizer 30-3-9 with Poly-S® Nitrogen & 2% Iron (from February to September), Best® Nitra King® 19-4-4 with 2.2% Iron (from October to November), and Best® Ammonium Sulfate 21-0-0 (from December to January). Together, the fertilizers contain nitrogen, phosphate, potassium, sulfur, iron, calcium, and chlorine. Nitrogen, phosphate, and potassium are major nutrients for plant growth. Sulfur, iron, calcium, and chlorine are minor nutrients for plant growth. The grub control (Nemasys® G) contains live nematodes to control the growth of pest larvae. The grub control is used in conjunction with surfactants (AquatrolsSixteen 90) for optimal effectiveness. Product sheets for the landscape additives are found in Appendix III-B. Gypsum (hydrated calcium sulfate), commonly used to promote soil hydraulic conductivity, is not used at the site.

3. METHODOLOGY

To evaluate the effects that recycled water irrigation may have on groundwater, it is necessary to characterize the groundwater conditions before and after recycled water application begins. Groundwater conditions before recycled water application were established by a water quality baseline sampling event for comparison with subsequent sampling events. One baseline sampling event was performed as part of this pilot study. The SCVWD also conducted three additional baseline sampling events prior to the pilot study, which were used to supplement the data. The pilot study subsequent sampling events monitored groundwater and pore water conditions as recycled water was applied, and were designed to observe the effects of recycled water as it migrated through the vadose zone and into the saturated zone. Results from the sampling were used to observe the constituent concentrations over depth and over time.

The constituents monitored in this pilot study were selected based on their presence in recycled water sources and the potential negative impact the constituent may pose to the beneficial uses of groundwater. An evaluation of recycled water constituents and their potential to impact groundwater was presented in Volume I of this report.

For support and comparison, findings from the bench test (originally presented in Volume II of this report) are included in the pilot study evaluation. Conclusions from the bench test, specifically whether or not attenuation was consistently observed for the constituent, were compared with the pilot study findings. The overall conclusions for this volume consider findings from both the bench test and pilot study.

3.1. Analytes

Each location sampled was tested for a set of constituents (shown in Table III-3-1) based on the findings from Volume I. Constituents were selected based on the potential negative impact the constituent may pose to the beneficial uses of groundwater. Specifically, constituents were selected based on the following criteria: 1) potential to degrade groundwater based on significantly higher concentrations in recycled water, 2) fate and transport characteristics (e.g., mobility, persistence), and 3) an established state or federal regulatory, action, or notification level indicating potential human health effects. Aldicarb sulfoxide, PHaCs, NDCs, NBBS, and trisphosphates, which were recommended for further monitoring from Volume I, were not included in the pilot study as a commercial laboratory to test for these constituents could not be identified. While these constituents were not monitored, the constituents that were included in the monitoring plan for the pilot study cover a wide characteristic range that strongly represents recycled water. In addition, bromide was included in the sampling list as a tracer.

VOCs, which were not recommended for further monitoring in Volume I, were included in the pilot study because the VOCs are reported as a part of the analysis (EPA 8260B) that also analyzes THMs.

Constituents including ethylenediaminetetraacetic acid (EDTA), surfactants (MBAS), nitrilotriacetic acid (NTA), perchlorate, cyanide, and terbuthylazine, which were initially analyzed in the pilot study, were later scaled down in monitoring scope because these constituents were not consistently found above detection limits in the recycled water during the pilot study or bench test. Further discussion of the monitoring changes for specific constituents is included in Section 4.1.

3.2. Analytical Laboratories

To cover the necessary analyses needed for this pilot study, three primary analytical laboratories were used: Curtis and Tompkins, Montgomery Watson Harza Laboratories, and EMLab P&K. All three are California state-certified laboratories. Specific analyses assigned to each laboratory are listed on Table III-3-1.

3.3. Data Evaluation

3.3.1. Mann-Kendall Trend Analysis

Data results were evaluated using a Mann-Kendall trend analysis. The Mann-Kendall trend analysis was evaluated over the entire pilot study period, from the baseline event to the last sampling event. Results for the the Mann-Kendall trend analysis are provided in Table III-4-4. The Mann-Kendall is a nonparametric statistical test that is used to assess trends over time. The procedure compares the most recent datum with results of the earlier sampling events. A +1 point is awarded if the most recent concentration is larger, or a

-1 point is awarded if the most recent concentration is smaller. Where the recent concentration is equal to the compared result, no point is awarded and the comparision is regarded as a tie. The total score for the time series data is called the Mann-Kendall statistic (S), which is then compared to a critical value, to test whether the trend in concentration over time is increasing ("up"), decreasing ("down"), or if no trend ("none" or "none - all ties") in concentration can be determined. Conditions set for the trend analysis include treating nondetect values at the reporting limit and using a five percent significance level (i.e. 95% confidence). A probability is also included in Table III-4-4 which indicates the level of uncertainty in the trend. A lower probability indicates high confidence of the resulting trend. The difference between "none" and "none – all ties" is that in the "none – all ties" case, all the values are equal to each other. In this data set, this occurs because all the values are below detection and are treated at the reporting limit which is consistent through the pilot study. A trend of "none" is reported when the concentrations fluctuate, and the trend direction cannot be determined with a confidence of 95%. Results of the Mann-Kendall analysis are discussed with the concentration data in Section 4.1. The Mann-Kendall analysis included the baseline data as part of the evaluation to represent conditions prior to recycled water irrigation. Any concentration changes in subsequent events were compared to the baseline data.

The Mann-Kendall analysis is a more statistically robust analysis compared to the percentage difference approach used for the bench test data in Volume II. Since only two sampling events were collected for the bench test, a Mann-Kendall analysis could not be performed on those data. The pilot study reported a sufficient volume of data for this analysis.

3.3.2. Quality Assurance/Quality Control

Quality assurance/quality control evaluations were performed for all laboratory reports. The following criteria were considered in evaluating data quality:

- Duplicate sample results should be within 25% of each other
- Field blank and method blank samples should not have constituents detected
- Recovery of surrogate analyses should be 80 to 120%
- Matrix and blank spike samples should have 50 to 150% recovery

- Spike and spike duplicate results should be within 35% of each other

These data quality indicators were used when method-specific quality control limits were not specified by the laboratory. Data that did not meet criteria resulted in data being disregarded or qualified, depending on the degree to which quality control was compromised. Qualified and/or disregarded data is flagged in Table III-4-1.

3.4. Sampling Frequency

The pilot study was implemented over a period of 18 months. A summary of events during the pilot study can be found in Table III-3-2.

3.4.1. Baseline Sampling Event

On May 19, 2008, prior to implementation of recycled water irrigation at the IDT site, samples were collected from the four existing monitoring wells and the recycled water source at SJ/SC WPCP to represent conditions prior to application of recycled water at the site. Additional baseline sampling on May 16-17, 2007, August 16, 2007, and December 20, 2007 was conducted by the SCVWD at the four existing monitoring wells. The additional baseline sampling was a subset of constituents monitored in the pilot study. Reporting limits were different from the pilot study for some of the constituents in the additional baseline monitoring. The baseline sampling was used to determine the pre-existing concentrations in the groundwater and the initial conditions of the recycled source water.

Additional analyses were added for the final baseline sampling event in May 2008, based on the results of Volume I of this study. An abbreviated analysis list was used for the prior baseline sampling events. Lysimeters were not part of the baseline sampling event because they were not installed until July 2008. The recycled water source was only sampled in the May 2008 baseline sampling event.

3.4.2. Subsequent Sampling Events

After the baseline sampling, eight sampling events took place over the course of the pilot study between October 27, 2008 and March 1, 2010. For each of these sampling events, thirteen locations were sampled: four existing groundwater monitoring wells (MW-1 to MW-4), eight lysimeters, and one at the selected recycled water source location as discussed in Section 2.1.2. The lysimeter samples were composited into two samples (L5-COMP, L10-COMP) as described in Section 2.2.2.5 to meet sample volume requirements.

Sampling events began approximately 50 days after recycled water irrigation had initiated. Each sampling event was initially scheduled approximately 50 days apart. The initial frequency was estimated using the geometric mean of the hydraulic conductivity of the shallow soil at the site. Two soil samples were collected at the IDT site as part of the bench test as described in Volume II, and analyzed for permeability. From these measured values (4.7×10^{-6} and 3.1×10^{-4} centimeters per second (cm/sec)), a geometric mean hydraulic conductivity of 3.8×10^{-5} cm/sec was calculated. This value is expected to be representative of the vadose zone across the site because of the observed vertical and horizontal homogeneity of soil types as discussed in Section 2.2.1. Based on this value, the irrigation water was expected to migrate downwards through the vadose zone at a maximum rate of 0.1 feet per day. Following the third sampling event, the sampling schedule was adjusted to sample every 75 days because downward migration appeared to be slower than predicted.

3.4.3. Sample Extraction for Lysimeters

In addition to compositing the lysimeters, the lysimeters were sampled in two sample extractions for each sample event due to large sample volume required and limited capacity of the lysimeters. The capacity of the lysimeter is 1500 mL. Therefore the maximum sample volume yielded from compositing four lysimeters is 6000 mL. However, a full set of analyses listed in Table III-3-1 requires approximately 8000 mL. To accommodate for the limited volume, an interim trip was made approximately three weeks following the initial sample extraction as shown in Table III-3-2. The interim extraction provided additional sample volume used to complete the analysis list. Interim samples were collected from all the lysimeters and were not composited with the initial samples. Appendix III-C contains the chain of custody forms indicating what analyses were done in each event. Lysimeters maintained a continuous vacuum to maximize the sample volume as needed by the study. Because water is stored in the chamber once it enters the lysimeter until time of sampling, time between storage and sampling may change the characteristics of the water from that of vadose zone water. Given the constraints of the lysimeter devices, it is assumed that the characteristic differences are minimal.

3.5. Sampling Protocol

3.5.1. Monitoring Well Sampling

Immediately before sampling each well, standing water was purged from the casing and gravel pack using electric submersible pumps. In each well, three casing volumes were purged prior to sampling, except in the case where the well was pumped dry during purging. The casing volume was determined before sampling by measuring the depth to water, subtracting that from the total depth of the well (45 feet for each well), and multiplying the water column height by 1.96 to obtain the casing volume in gallons. The calculation of the 1.96 conversion factor is shown below.

$$
\begin{aligned}
3\,\text{casing volumes (gal)} &= 3\left[\text{casing cross-sectional area }(\text{ft}^2)\right]\left[\text{water column height (ft)}\right]\left[\frac{7.48\,\text{gal}}{1\,\text{ft}^3}\right] \\
&= 3\pi\left[\text{casing radius (ft)}\right]^2\left[\left[\text{well depth}\right]-\left[\text{water table depth}\right]\right]\left[\frac{7.48\,\text{gal}}{1\,\text{ft}^3}\right] \\
&= 3\pi\left[\frac{2}{12}\,\text{ft}\right]^2\left[\frac{7.48\,\text{gal}}{1\,\text{ft}^3}\right]\left[\left[\text{well depth}\right]-\left[\text{water table depth}\right]\right] \\
&= \left[1.96\,\frac{\text{gal}}{\text{ft}}\right]\left[\left[\text{well depth}\right]-\left[\text{water table depth}\right]\right]
\end{aligned}
$$

All four monitoring wells at the site have the same casing radius (2 inches) and well depth (45 feet). During the purging process, pH, temperature, and conductivity were monitored to verify that the readings were steady before sample collection. The final steady-state measurements of these parameters were recorded on the well sampling form, along with other field measurements listed in Table III-3-1 (ORP, dissolved oxygen, total chlorine).

Purge water from the monitoring wells was reapplied on the IDT site landscape in an area not located near the lysimeters or monitoring wells (e.g. along the south border or northernmost corner of the parking lot).

3.5.2. Lysimeter Sampling

Each installed lysimeter has two ¼-inch diameter tube attachments, one to apply vacuum or pressure and one for fluid return. To obtain a sample, the fluid return tube is sealed, and a vacuum is applied to the vacuum/pressure tube. This action moves the water from the lower chamber where water enters the lysimeter to the upper chamber where it can be stored and extracted. To collect the sample, the fluid return tube is opened and inserted into the sample container. A pressure is applied to the vacuum/pressure tube, and the sample water is forced up through the fluid return tube. The vacuum was reapplied immediately after sample extractions, and on a regular basis between sampling events to maintain negative pressure in the lysimeters for the duration of the study.

Lysimeters were purged once, prior to the first sampling event, to remove the residual water left behind during installation of the lysimeter.

3.5.3. Recycled Water Source Sampling

For the May 2008 baseline sampling event, recycled water could not be sampled directly at the pilot study site because the irrigation system was not yet connected to the recycled water source. Therefore, the baseline sample representing the recycled water source was collected from the SJ/SC WPCP, located approximately 15 miles northwest of the pilot study site. Starting with the first monitoring event after recycled water application began, the irrigation source samples were collected by using an attachment on one of the spray heads of the irrigation system. Using this method, the samples represent the irrigation source prior to any volatilization or photodegradation that would occur as a result of the use of spray irrigation.

3.5.4. Quality Control Samples

For quality assurance/quality control (QA/QC) purposes, a duplicate water sample was collected for every 20 field samples to evaluate precision in the laboratory and sampling procedures. Similarly, a blank water sample was collected for every 20 field samples. One rinseate blank was also collected during the pilot study to evaluate cross contamination by sampling equipment. Blank samples were used to evaluate any potential false positives in the samples. All QA/QC samples were analyzed by the laboratory using the same preparation and analytical methods.

3.5.5. Documentation

A water sampling log was completed for each sample collected, except for quality control samples. Water sampling logs and chains of custodies are included in Appendix III-C. All purging information, as well as field measurements and associated quality control samples are recorded on the water sampling log. The samples were also recorded on a chain of custody form sent with the samples to the laboratory. Logs for recharging the lysimeters are included in Appendix III-D.

4. RESULTS

4.1. Chemical Results

This section discusses the analytical results of the constituents of recycled water that were monitored. Chemical results discussed in this section may be found in Table III-4-1. Minimum and maximum range data and Mann-Kendall trend analyses are included in this section with the text. For minimum and maximum range data, the baseline includes four baseline data events: May 19, 2008; December 20, 2007; August 16, 2007; and May 16-17, 2007. Sample event numbers refer to the sequence after recycled water implementation (e.g. 1st event is the first event after recycled water application began).

In addition, charts graphically displaying the chemical results are provided in Figures III-4-1 to III-4-48. Concentrations are plotted in these figures over time at each location, and also over depth for each sampling event (with average concentrations from the monitoring wells used to represent the concentrations at 35 feet). Data results with no detections are treated as zero in the figures. A legend of data qualifiers and results of QA/QC data are provided in Tables III-4-2 and III-4-3 respectively. A table summarizing the Mann-Kendall trend analyses is provided in Table III-4-4. Original lab reports of the constituent analyses are found in Appendix III-E.

For each constituent, the concentrations were evaluated with respect to the following questions:

- Does the constituent concentration consistently change with depth, indicating possible attenuation through the soil?
- Is there a clear increasing trend in the concentrations in pore water or groundwater over time, suggesting a potential impact to groundwater in the short-term or long-term?
- Is the constituent present only in recycled water or are there other sources in the pilot study (e.g. naturally occurring, or derived from fertilizer or soil amendments)?

These questions address the overall goals of this study, and will be used to determine which constituents have the potential to impact groundwater within the Santa Clara and Llagas Groundwater Subbasins.

Chemical results covered in this section discuss water from three categories: irrigation water (recycled water), vadose zone, and groundwater. Irrigation water is represented by samples collected from the irrigation system, pore water from the vadose zone is represented by the lysimeters, and groundwater is represented by monitoring wells MW-1 to MW-4.

In the vadose zone, soil is not fully saturated so that pore water is exposed to air and potential for volatilization is present. Microbial activity in the upper vadose zone region is high. Near the surface of the soil, in the presence of vegetation, root uptake serves as a sink for nutrients found in recycled water. Soil interacts with the pore water through soil sorption/desorption and filtration processes. Evapotranspiration of water may occur, particularly in the upper vadose zone. In addition to irrigation water, rain water is also a source for water found in the vadose zone. Due to water losses and gains from these processes, concentrations of conservative constituents from the irrigation to the vadose zone are expected to concentrate by a factor of two (see section 4.3). Results discussed in Section 4.1 take into account the concentration effect between irrigation water and pore water.

The shallow groundwater is a fully saturated zone. The volatilization pathway is not significantly present at this stage. Groundwater is a mixture of pore water percolating from the vadose zone and groundwater currently present or flowing onsite through the saturated zone, which may include recharge from nearby Coyote Creek. The extent of dilution at this site is not known.

General Water Quality

4.1.1.1. pH and Alkalinity

Measured pH remained in a neutral or near neutral range in the recycled water, pore water, and groundwater. Generally, pH in the irrigation and the pore water were slightly higher than in the groundwater. The pH of recycled water fell within the pH range expected from the previous data analysis in the literature review and agrees with the values obtained from the bench test. The groundwater pH was observed in the lower end of the pH range expected from the data analysis (see Volume I). Because the pH of groundwater is also near neutral, groundwater pH would not likely be affected by the irrigation of recycled water. The near neutral pH across all locations indicates that recycled water did not cause major shifts in pH in either the vadose zone or the groundwater. The pH in the bench test effluent and influent were also found to be near neutral.

Summary of Median [Minimum - Maximum] Data for pH (pH unit)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	7.34 [6.75 - 7.94]	-	-	6.75 [6.24 - 7.4]
Sample Events		7.26 [6.43 - 7.76]	7.22 [6.55 - 7.84]	6.77 [6.41 - 6.9]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

Alkalinity was highest in the pore water followed by the groundwater, and lowest in the recycled water. Alkalinity in the recycled water was within the expected range from the Volume I data analysis and agrees with the values obtained from the bench test. Alkalinity in the groundwater was in the higher end of the alkalinity range expected from the data analysis. The primary form of alkalinity was bicarbonate. Contributions to alkalinity from other forms such as phosphate, sulfides, or borates were minimal. Alkalinity increased in concentration from the recycled water to the pore water likely as a result from leaching of naturally occurring carbonate material in the soil. In the bench test, alkalinity was found not to be significantly different in concentration in the influent and effluent samples potentially due to the shorter distance of percolation and shorter monitoring time frame.

Alkalinity is a measure of the buffering capacity of water. The high alkalinity in the pore water suggests that the vadose zone is resistant to pH changes.

Summary of Median [Minimum - Maximum] Data for Alkalinity, Total (as CaCO3) (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	170 [170 - 210]	-	-	351.5 [299 - 510]
Sample Events		620 [470 - 720]	690 [660 - 730]	368 [240 - 490]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.1.2. Total Dissolved Solids

Total dissolved solids (TDS) or Total Filterable Residue (at 180 °C) concentrations in recycled water fell within the expected range from the Volume I data analysis. TDS in the recycled water, lysimeters and majority of groundwater wells at IDT were above the national secondary drinking water standard of 500 mg/L. TDS was observed to be highest in L5-COMP followed by L10-COMP, recycled water, and groundwater. TDS in the five-foot lysimeters was initially high relative to the recycled water possibly as a result of the contribution of material leached from the soil. The increase may also be as a result of water loss from evapotranspiration and thus concentrating the constituent. In the bench test, TDS concentrations between the influent and effluent were not significantly different suggesting low attenuation. TDS in L10-COMP was lower than in the L5-COMP. Over time, TDS in the L5-COMP decreased while TDS in recycled water appeared stable relative to the concentration changes in the pore water. TDS in the groundwater remained relatively stable through the study relative to changes in the pore water. While TDS groundwater remained relatively stable, monitoring should be continued to ensure that recycled water does not further impact groundwater relative to secondary drinking water standards.

Summary of Median [Minimum - Maximum] Data for Total Dissolved Solids (TDS) (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	740 [690 - 880]	-	-	549 [380 - 738]
Sample Events		1650 [1240 - 2180]	1075 [1010 - 1280]	560 [400 - 760]
Mann-Kendall Trend	None	Down	Down	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.1.3. Dissolved and Total Organic Carbon

Dissolved organic carbon (DOC) and total organic carbon (TOC) were observed to be similar in concentrations to each other in most sampling locations. TOC and DOC were observed to be highest in L5-COMP, followed by recycled water, L10-COMP, and groundwater. In only L5-COMP, TOC and DOC were observed to be very high in the first sampling event followed by a reduction to levels similar to that of recycled water. The initial peak in organic carbon observed in L5-COMP suggests an initial desorption of material resulting from the switch to recycled water as an irrigation source, which was similar to the behavior of TDS. TOC and DOC remained stable thereafter. In the bench test, TOC and DOC displayed a similar behavior of initial high effluent concentrations followed by more subsided concentrations in the later event.

The lower concentrations of organic carbon in the L10-COMP relative to L5-COMP suggest removal occurring with depth potentially due to filtering, adsorption to soil, and aerobic respiration.

The only data qualifier flag that was applied to the DOC results in the pilot study was the "B" flag, which was applied to one sample from the L5-COMP location. A discussion of each flag is found in Section 4.2.4. Although there is some reduced confidence in the qualified data, only a few data points were affected and those qualified results are consistent with other samples from the same locations. Therefore, the data are still appropriately useful for comparative purposes and are therefore used for evaluation in this study.

Summary of Median [Minimum - Maximum] Data for Dissolved Organic Carbon (DOC) (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	6.2 [4.8 - 7.2]	-	-	1.25 [0.44 - 1.6]
Sample Events		7.8 [6.2 - 78]	3.45 [2.7 - 6.4]	ND 1 [ND 1 - 2.1]
Mann-Kendall Trend	Down	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

Summary of Median [Minimum - Maximum] Data for Total Organic Carbon (TOC) (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	6.4 [5.4 - 8]	-	-	0.69 [0.44 - 0.91]
Sample Events		7.55 [5.8 - 73]	3.35 [2.9 - 6.6]	0.595 [ND 0.5 - 0.88]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.1.4. Redox Potential and Dissolved Oxygen

Generally, oxidation reduction potential (ORP) at all sample locations was stable, maintaining measurements between 50 and 200 mV. ORP measurements in the lysimeters correlated strongly with measurements in recycled water, beginning with the third sampling event. ORP in the recycled water was high in comparison to groundwater in the baseline event. ORP data suggest that there were no major shifts in redox conditions. ORP measurements in the bench test also suggested that there were no major shifts in redox conditions.

Summary of Median [Minimum - Maximum] Data for ORP (mV)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	126 [78 - 417]	-	-	183 [174 - 192]
Sample Events		112 [25 - 182]	100.5 [69 - 179]	114.5 [68 - 915]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: Down MW-4: None

Dissolved oxygen (DO) concentrations in groundwater water remained at 0.01 mg/L or above throughout the pilot study, indicating oxic conditions. DO measurements in groundwater for the baseline sampling events were also low but were always 0.01 mg/L or higher. DO in the recycled water remained at concentrations above 0.01 mg/L. DO in the L5-COMP and L10-COMP locations were measured but are not considered representative because compositing of samples could not be completed without some exposure to air. Groundwater DO remained above 0.01 mg/L through the pilot study suggesting anoxic conditions are unlikely to occur as a result of recycled water used for irrigation at the site. In the bench test, the system also maintained oxic conditions.

Summary of Median [Minimum - Maximum] Data for Dissolved Oxygen (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	5.69 [0.04 - 8.1]	-	-	0.045 [0.01 - 0.05]
Sample Events		8.315 [5.84 - 11.3]	8.365 [6.21 - 9.89]	1.315 [0.51 - 4.94]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.1.5. Total Chlorine

Total chlorine was measured in the pilot study because it is an easily tested field measurement and can provide useful information with regard to bacterial counts. Total chlorine was unexpectedly higher in the groundwater than in the other locations. It is unclear why chlorine results were higher in the groundwater, but the median heterotrophic plate count was found to be lower in the groundwater compared to the recycled water and pore water during the pilot study. Consistency in measurements between sampling events suggests no issues with QA/QC. The baseline total chlorine concentration in recycled water was high because the sample was taken near the treatment plant compared to the total chlorine concentration for the subsequent sample events which were taken at the IDT site. Levels of total chlorine appear to diminish as recycled water travels from the plant to the site. Because of low levels of total chlorine in the recycled water relative to groundwater, total chlorine does not appear to be a concern for groundwater impacts due to recycled water irrigation.

In the bench test, detection of total chlorine in the influent and soil core effluent was overall sporadic.

Summary of Median [Minimum - Maximum] Data for Chlorine, Total (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	0.13 [0.04 - 8.8]	-	-	-
Sample Events		0.125 [0.07 - 0.42]	0.13 [0.04 - 1.05]	0.89 [0.21 - 2.2]
Mann-Kendall Trend	None	None	None	MW-1: Down MW-2: Down MW-3: None MW-4: None

4.1.2. Anions and Cations

4.1.2.1. Chloride

Generally chloride was highest in recycled water followed by L5-COMP, L10-COMP and groundwater. Chloride concentrations in recycled water were stable over time relative to changes in the pore water. Chloride in L5-COMP and L10-COMP steadily increased over time. Chloride concentrations in the lysimeters do not appear to have reached equilibrium during the pilot study, and may have the potential to increase further. No mechanisms for removal of chloride were identified in the literature review and the mobility of chloride as seen in the data suggests that mechanisms for chloride removal are minimal. Most chloride samples were below the secondary drinking water standard for chloride of 250 mg/L. Chloride was detected above 250 mg/L only once in the recycled water source and once in L5-COMP during the pilot study.

In groundwater, chloride at MW-3 increased toward the end of the study indicating a potential long term effect on groundwater. Chloride in the other groundwater wells remained stable.

In the bench test, chloride did not change significantly between influent and effluent samples, suggesting also that attenuation of chloride was low.

Summary of Mean [Minimum - Maximum] Data for Chloride (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	200 [190 - 280]	-	-	26 - 72
Sample Events		125 [86 - 270]	81 [71 - 130]	25 - 95
Mann-Kendall Trend	None	Up	Up	MW-1: None MW-2: None MW-3: Up MW-4: None

4.1.2.2. Sulfate

Sulfate was found to be highest in L5-COMP followed by L10-COMP, recycled water, and groundwater. The increase in sulfate concentrations from recycled water to the pore water at five feet bgs was likely caused by sulfate found in the fertilizer. The heaviest sulfate-containing fertilizer was applied in December and January. Sulfate in the fertilizers used in the other months were lower in concentration. The contribution of sulfate from this source to pore water appears to be significantly higher than the contribution from recycled water. Some increase may also be as a result of water loss from evapotranspiration and thus concentrating the constituent. At ten feet bgs, sulfate concentrations were decreased significantly from five feet bgs. At the groundwater depth, sulfate concentrations decreased from the ten foot depth, although the decrease may be due to dilution in groundwater. Decreases of sulfate in the pore water over depth may have occurred from mineralization. The plant uptake pathway is not likely to affect the analysis to a large degree, and absorption of sulfate requires positively charged surfaces which are not common in mediterranean climates such as the study area. Sulfate concentrations in the lysimeters were found above secondary drinking water standard of 250 mg/L.

Sulfate concentrations in recycled water and groundwater were stable over time relative to the changes in the pore water. Sulfate in L5-COMP and L10-COMP steadily decreased over time. The result may be from the use of a more sulfate-heavy fertilizer in January and December than the rest of the year. In the bench test, sulfate generally exhibited no significant differences in concentration between influent and effluent water samples.

Summary of Median [Minimum - Maximum] Data for Sulfate (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	95 [89 - 110]	-	-	69.45 [40 - 129]
Sample Events		545 [260 - 980]	195 [130 - 320]	60.5 [34 - 80]
Mann-Kendall Trend	None	Down	Down	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.2.3. Bromide

Bromide was highest in concentration toward the surface. Bromide concentrations in recycled water and the lysimeters were similar, and correlated strongly over time starting with the fourth sampling event. Groundwater bromide concentrations were lower than the recycled water and lysimeter concentrations throughout the pilot study. It should be noted that the reporting limit for bromide for the baseline sampling event was 0.5 mg/L, and all bromide concentrations (for groundwater and recycled water) were below detection. Figure III-4-12A shows these points as zero. Subsequent sampling events had a bromide reporting limit of 0.05 to 0.065 mg/L, and most concentrations in all sources were detected between 0.05 and 0.5 mg/L. In the bench test, bromide was below detection in the influent and effluent samples. The laboratory reporting limit in the bench test was 0.5 mg/L.

The only data qualifier flag that was applied to any bromide results was the "J" flag, which was applied to a single concentration from the L10-COMP location in the first sampling event. A discussion of the "J" flag is found in Section 4.2.4. The "J" flag reduces confidence in the quantification of the constituent but does not negate the fact that the constituent was detected. The flagged concentration is consistent with other concentrations from this location, and the qualified data does not affect the other results or affect the bromide findings above.

Summary of Median [Minimum - Maximum] Data for Bromide (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	0.27 [ND 0.5 - 0.38]	-	-	0.17 [ND 0.5 - 0.32]
Sample Events		0.26 [0.16 - 0.43]	0.235 [0.15 J - 0.3]	0.165 [ND 0.065 - 0.26]
Mann-Kendall Trend	None	None	Up	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.2.4. Cyanide

Cyanide, which was monitored only in the recycled water, was detected infrequently and near the reporting limit. Cyanide was monitored only in the recycled water as recommended from the bench test conclusions to limit the monitoring of constituents that were not frequently detected. In the bench test, cyanide was below detection in both the influent and effluent. The reporting limit for cyanide ranged from 0.005 to 0.01 mg/L in the pilot study and bench test. The range is below the California MCL for cyanide of 0.15 mg/L. Because cyanide is not prominent in the recycled water source, the attenuation behavior was not observed.

Summary of Median [Minimum - Maximum] Data for Cyanide (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	ND 0.01 [ND 0.005 - 0.02]	-	-	ND 0.005 [ND 0.005 - ND 0.005]
Sample Events		-	-	-
Mann-Kendall Trend	None	-	-	-

4.1.2.5. Boron

Boron was highest in recycled water followed by the lysimeters, and lowest in the groundwater. Boron concentrations across all locations did not appear to change significantly over time. Boron concentrations decreased from recycled water to the pore water at five foot bgs, possibly due to plant uptake. Concentrations of boron at the five foot and ten foot depth did not appear to change significantly. Boron in groundwater was relatively stable through the pilot study. The results suggest that boron in the recycled water may have not yet reached groundwater. In the bench test, boron concentrations in the influent and effluent were not significantly different, suggesting that the soil cores had minimal effect on this constituent.

Summary of Median [Minimum - Maximum] Data for Boron (µg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	460 [380 - 480]	-	-	189 [140 - 229]
Sample Events		285 [250 - 400]	285 [230 - 330]	190 [130 - 240]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.2.6. Potassium

Potassium was highest in recycled water followed by L5-COMP, L10-COMP, and groundwater, indicating a consistent decrease in concentration with depth. Potential mechanisms for the decrease include plant uptake and sorption. In clay soils, potassium is preferentially sorbed due to a high charge to size ratio. Results are similar to the bench test, where potassium exhibited significant removal in the soil cores. In addition to recycled water, minor amounts of potassium from fertilizer contributed to potassium at the soil surface.

The Mann-Kendall trend analysis did not indicate statistically significant upward or downward trends of potassium in recycled water, groundwater, or L5-COMP. In L10-COMP, potassium decreased over time particularly in the early portion of the pilot study. The decreasing trend in the early part of the pilot study may be the result of the fluctuation observed in the recycled water. Data suggest that there is minimal potential for potassium to negatively impact groundwater.

Summary of Median [Minimum - Maximum] Data for Potassium (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	15 [12 - 19]	-	-	0.83 [ND 0.5 - 2.3]
Sample Events		5.2 [2.5 - 9.3]	1.35 [1.1 - 3.6]	0.605 [ND 0.5 - 1.1]
Mann-Kendall Trend	None	None	Down	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.2.7. Sodium Adsorption Ratio

The sodium adsorption ratio (SAR), which is calculated from calcium, magnesium, and sodium data, describes the concentration of sodium relative to calcium and magnesium. A high level of SAR in the recycled water relative to the soil has the potential to cause clay swelling and reduce hydraulic conductivity. A decrease of SAR in the vadose zone with respect to depth suggests that sodium ions are replacing calcium and magnesium ions in the intra-particle clay surfaces, which causes clays to swell. A further background discussion of SAR may be found in Section 3.1 of Volume I. SAR was observed to be highest in recycled water and L5-COMP, followed by L10-COMP and groundwater. The SAR values in the groundwater and L10-COMP were stable over time, and SAR in L10-COMP remained slightly higher but similar to that of groundwater throughout the pilot study. SAR in the recycled water and L5-COMP were stable to an extent with moderate variability. SAR in recycled water and L5-COMP were similar suggesting that ions in the pore water were in equilibrium with ions in the clay surfaces in the first five feet over the study period. This suggests that clays may have been have swelled to some degree in the first five feet prior to the pilot study. The difference in SAR between L5-COMP and L10-COMP indicates the pore water composition is different. This suggests a clay swelling wave front occurring between the five and ten foot depth during the study period. The presence of clay swelling may present a concern for soil drainage. However, because the effect of clay swelling could not be measured, the level of impact could not be determined.

Summary of Median [Minimum - Maximum] Data for SAR (unitless)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	4.13 [3.3 - 5.11]	-	-	0.82 [0.74 - 0.95]
Sample Events		3.58 [2.68 - 4.17]	1.12 [0.98 - 1.22]	0.8 [0.62 - 0.92]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.2.8. Calcium

Calcium was highest in L5-COMP, followed by L10-COMP, groundwater, and recycled water which had consistently the lowest concentration. Pore water at the five-foot depth had calcium concentrations significantly higher than recycled water. The high levels of calcium found in L5-COMP are potentially caused by displacement in the soil by exchange of calcium for sodium within the uppermost five feet. The increase at the IDT site may also be as a result of water loss from evapotranspiration and thus concentrating the constituent. Calcium in the pore water at the ten-foot depth was lower than at the five-foot depth. The difference in concentrations between the two depths diminished over time. Calcium decreased over time seen in the L5-COMP which is potentially a result of an initial flushing of calcium from the surface soil. A subsequent increase in calcium concentrations in groundwater from flushing was not consistently observed during the pilot study. The removal over time lessened as the system approached equilibrium. In the bench test, calcium behaved in a similar manner in the soil cores, exhibiting an initial concentration increase in the effluent followed by a return to influent levels.

Calcium concentrations in groundwater and recycled water were stable over time. In addition to recycled water, minor amounts of calcium from fertilizer (Best® Nitra King® 19-4-4 with 2.2% Iron) applied regularly in the fall (October and November) contributed to calcium at the soil surface. Calcium contributes to the total dissolved solids of the system.

Summary of Median [Minimum - Maximum] Data for Calcium (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	54 [44 - 64]	-	-	87.75 [62 - 122]
Sample Events		180 [120 - 270]	150 [120 - 170]	85 [49 - 120]
Mann-Kendall Trend	None	Down	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.2.9. Magnesium

Magnesium was highest in L10-COMP followed by L5-COMP, groundwater, and recycled water. Higher magnesium concentrations in the lysimeters compared to the recycled water maybe a result of displacement in the soil by exchange of magnesium for sodium. At the groundwater depth, magnesium concentrations were consistently lower than in L10-COMP. The increase from recycled water to vadose zone water at the IDT site may also be as a result of water loss from evapotranspiration and thus concentrating the constituent. In the bench test, magnesium behaved in a similar manner in the soil cores, exhibiting an initial concentration increase in the effluent followed by a return to levels closer to the influent concentration.

Magnesium concentrations in groundwater and recycled water locations were generally stable over time. Magnesium in L5-COMP and L10-COMP decreased 34% and 25% respectively over the 18-month study period. The gradual decrease over time seen in the lysimeters suggests an initial flushing of the magnesium leached from the soil, followed by a gradual adjustment to equilibrium. A subsequent increase in magnesium concentrations in groundwater from flushing was not consistently observed during the pilot study. Magnesium concentrations in recycled water are consistently lower than those observed in the subsurface samples. Magnesium contributes to the total dissolved solids of the system.

Summary of Median [Minimum - Maximum] Data for Magnesium (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	30 [25 - 39]	-	-	52.95 [36 - 73.1]
Sample Events		81.5 [53 - 100]	110 [98 - 130]	51.5 [30 - 73]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.2.10. Sodium

Sodium concentrations were highest in L5-COMP followed by recycled water, L10-COMP, and groundwater. Sodium levels increased from recycled water to L5-COMP potentially due to water loss from evapotranspiration. Sodium levels decreased in the pore water from the five-foot depth to the ten-foot depth. At the groundwater depth, sodium decreased modestly relative to the ten foot depth. Over time, sodium concentrations in all locations were stable. In the bench test, sodium generally exhibited little to no change in concentrations in the influent and core effluent samples. The differences in observations seen between the bench test and pilot study may potentially be due to the bench test being closer to equilibrium with respect to sodium concentrations compared to the pilot study. Sodium also contributes to the total dissolved solids of the system.

Summary of Median [Minimum - Maximum] Data for Sodium (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	140 [120 - 210]	-	-	40.55 [32 - 47.8]
Sample Events		240 [140 - 290]	72.5 [63 - 87]	37.5 [23 - 48]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.3. Nutrients

4.1.3.1. Phosphate- Total as P

Phosphate was highest in the recycled water compared to the pore water and groundwater. Phosphate from fertilizer applied onsite may have also contributed to concentrations found in the subsurface in addition to the phosphate from recycled water.

Phosphate concentrations found in the groundwater were similar in magnitude to those found in the lysimeters with the exception of a few isolated high concentrations. Phosphate concentrations in MW-2 (10/2008) and in MW-1 (12/2009 and 3/2010) were higher than in recycled water, and were not consistent with either the other groundwater phosphate concentrations on those dates or with the phosphate concentrations from those wells on other sampling dates. With respect to depth, phosphate decreased between the applied recycled water and the pore water at five-foot depth. A significant cause of this concentration reduction may be attributed to root uptake of this nutrient and precipitation of phosphate. Between five and ten feet, an additional slight removal of phosphate was observed. In the bench, phosphate behaved similarly, exhibiting a significant decrease from the influent samples to the effluent samples. The Mann-Kendall trend analysis did not indicate any statistically significant upward or downward trends over time.

Considering the level of phosphate attenuation within the upper ten feet of soil at the IDT site, phosphate appears to have minimal potential to impact groundwater.

Summary of Median [Minimum - Maximum] Data for Phosphate, Total as P (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	0.32 [0.21 - 0.62]	-	-	-
Sample Events		0.0485 [0.031 - 0.21]	0.042 [ND 0.03 - 0.062]	0.0625 [ND 0.03 - 0.86]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.3.2. Nitrate and Nitrite

Nitrate was highest in recycled water followed by groundwater, L10-COMP, and L5-COMP. With respect to depth, nitrate decreased dramatically at the five-foot depth compared to the recycled water, likely as a result of root uptake, even with contributions of nitrate from fertilizer to the soil surface.

Comparing the five and ten foot depth results, nitrate showed a moderate increase with depth in the pilot study. Nitrate concentrations at ten feet and groundwater are similar. The increase in nitrate observed between the five and ten foot depth is suspected to be a result of nitrate returning to equilibrium after depletion near the surface due to root uptake. Nitrate concentrations in the recycled water appeared generally stable with moderate fluctuation.

Over time, nitrate in the pore water increased slightly as seen in L10-COMP. Generally, nitrate in the groundwater did not show any statistically significant upward or downward trend. MW-2 was an exception to this case where nitrate trend was downward.

In the bench test, nitrate concentrations suggested that there was removal of nitrates in the soil even though the root uptake pathway was not present. Those changes may have been caused by nitrate transformation.

Summary of Median [Minimum - Maximum] Data for Nitrate as N (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	10 [7.7 - 15]	-	-	5.65 [3.3 - 10]
Sample Events		1.34 [ND 0.1 - 2.3]	2.25 [1.7 - 3.4]	2.95 [1.6 - 8.2]
Mann-Kendall Trend	None	None	Up	MW-1: None MW-2: Down MW-3: None MW-4: None

Nitrite concentrations were found to be highest in recycled water. Nitrite was detected only once in the groundwater and was not at all detected in the lysimeters. The behavior suggests transformation of nitrites to nitrates by nitrifying bacteria in the initial depth of soil. At the five foot depth, nitrite concentrations were at levels below detection. Given the decrease in nitrate concentrations in the vadose zone (likely due to root uptake) and the lack of nitrite in the subsurface, neither of these constituents appears to have the potential to impact groundwater as a result of recycled water application for irrigation. Note that there is mobility of nitrate when the root uptake pathway does not capture all the nitrogen. This may occur when fertilizer is over applied and/or when vegetation is absent. In these cases, excess nitrate can travel to groundwater.

Summary of Median [Minimum - Maximum] Data for Nitrite as N (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater

Sample Events		ND 0.05 [ND 0.05 - ND 0.1]	ND 0.05 [ND 0.05 - ND 0.1]	ND 0.05 [ND 0.05 - 0.15]
Mann-Kendall Trend	None	Down	None	MW-1: None MW-2: None MW-3: None MW-4: None

4.1.4. Anthropogenic Compounds

4.1.4.1. Trihalomethanes (THMs)

THM concentrations (bromodichloromethane, bromoform, chloroform, and dibromochloromethane) were consistently found to be highest in the recycled water. With respect to depth, the concentrations of all THMs decreased dramatically comparing recycled water to the pore water at five feet bgs suggesting effective removal in the soil. Below five feet, THMs were detected infrequently. THM removal could be partly attributed to volatilization from the irrigation spray process and in the vadose zone. THMs were not detected in the groundwater throughout the pilot study. THMs, specifically bromodichloromethane and chloroform, were only once detected in the lysimeters in September 2009 (sixth sampling event). THMs were not detected in the pore water in the subsequent events.

In the bench test, THMs exhibited a similar behavior. Generally, THMs in the effluent samples were lower in concentration than the influent samples.

Overall, the lack of THMs beyond five feet suggests a significant level of attenuation in the soil and minimal potential to impact groundwater.

Summary of Median [Minimum - Maximum] Data for Bromodichloromethane (µg/L)

4.1.4.2. Volatile Organic Carbons (VOCs)

Volatile organic carbons (VOCs), excluding THMs, were not detected in the recycled water. VOCs, including those discussed in Volume I (xylenes and carbon tetrachloride), were not detected in recycled water or the other sample locations. VOCs were not recommended for further monitoring in Volume I, but were included in the pilot study because they are reported as a part of the analysis (EPA 8260B) that also analyzes THMs. Trichloroethylene, cis-1,2-dichloroethene, and Freon 113 were detected in the groundwater.The source of trichloroethylene, cis-1,2-dichloroethene, and Freon 113 in the groundwater is not known, but these VOCs and its parent products were not detected in the recycled water and hence are not are not a result of recycled water application. The lack of detection indicates that VOCs did not pose a concern for groundwater impacts due to recycled water irrigation during the pilot study.

4.1.4.3. Haloacetic Acids (HAA6)

Haloacetic Acids (HAA6) include bromochloroacetic acid (BCAA), dibromoacetic acid (DBAA), dichloroacetic acid (DCAA), monobromoacetic acid (MBAA), monochloroacetic acid (MCAA), and trichloroacetic acid (TCAA). The most prominent HAA6 in recycled water was DCAA followed by TCAA, BCAA, MCAA, and DBAA. MBAA was not detected in any samples (recycled water source, monitoring wells, or lysimeters) during the pilot study.

Throughout the pilot study, TCAA and BCAA were detected only in recycled water, and not in any of the subsurface samples. MCAA, DCAA, and DBAA were detected in the lysimeters from September to December 2009, approximately 12 to 14 months after recycled water implementation. The appearance of these constituents in the lysimeters well into the study period indicates a slow migration through the vadose zone. In groundwater, only one HAA6 was detected throughout the pilot study. MCAA was detected in groundwater at MW-2 in the final sampling event. No other HAA6 constituents were detected in the groundwater. In the bench test, HAA6 were mixed in results exhibiting increases and decreases in the influent and effluent samples. The varying results in the bench test were attributed to fluctuative concentrations of HAA6 in the recycled water influent. Attenuation of HAA6 in the bench test was not well observed. From the pilot study, it appears that concentrations of HAA6 may continue to increase further over time. Overall, HAA6 was detected in the lysimeters toward the end of the pilot study and suggests potential to impact pore water and groundwater over longer time frames.

Data qualifier flags that were encountered in the haloacetic acids results in the pilot study include the "J" and "P" flags. A discussion of the flags is found in Section 4.2.4. Both of these flags reduce confidence in the quantification of the constituent concentrations but do not negate the fact that the constituent was detected in those samples. Since the above findings rely more on the presence of HAA6 rather than the quantified concentrations, these findings are not affected by the qualified data.

Summary of Median [Minimum - Maximum] Data for Bromochloroacetic Acid (µg/L)

4.1.4.4. N-Nitrosodimethylamine (NDMA)

NDMA concentrations were found to be highest in recycled water samples followed by lysimeters and the groundwater. The NDMA concentrations in recycled water measured at the site varied from 240 to 460 ng/L. The concentration in the recycled water sample collected directly from the SJ/SC WPCP plant for the baseline event was 112 ng/L. A previous study reported NDMA levels at the SJ/SC WPCP plant ranging from 50 to 360 ng/L (Sedlak et al., 2005). NDMA concentrations decreased dramatically between the recycled water source and the pore water at five feet bgs. The majority of this removal is suspected to be caused by volatilization during application by spray irrigation, where the water receives the most exposure to the atmosphere. Removal can also occur from degradation, plant uptake from the soil, and gas phase diffusion in the soil (Gan et al., 2006, Arienzo et al. 2006). However, volatilization in the vadose zone is reduced in soils that have high water content because of less exposure to air in the pore spaces. The clayey soils at the pilot study site appear to be moist, however this was not measured. Installation of soil moisture probes in future studies may provide information for correlation to NDMA volatilization.

NDMA concentrations at five feet and ten feet were similar. NDMA was detected in the pore water starting with the first sampling event, but the pore water concentrations gradually declined over time as seen in L10-COMP. NDMA in MW-1 showed a statistically significant upward trend over time. On three occasions, NDMA was found in the pore water samples above the California notification level for NDMA of 10 ng/L.

NDMA was detected in the groundwater starting with the fourth sampling event at concentrations near the laboratory reporting limit of 2 ng/L. By the seventh and eighth sampling events, NDMA was detected at low concentrations in three of the four monitoring wells. The NDMA concentrations in groundwater remained below the notification level throughout the pilot study.

Data qualifier flags that were encountered in the NDMA results in the pilot study include the "D," "BB," "BD," "L3," "S7," and "R4" flags. A discussion of the flags is found in Section 4.2.4. Some of these qualifiers ("BB", "BD", "L3") only affected certain samples from the second sampling event. Of the affected samples, all were below detection except one (IDT source), and the qualified concentration was similar to the other concentrations in the IDT source. The "D" flag only affected one sample from the IDT source in the fifth sampling event, and that result was also consistent with other concentrations in the IDT source. The "S7" and "R4" flags raise concerns regarding the accuracy of concentrations. However, both of these flags were only applied to samples where NDMA was not detected. Therefore, the accuracy does not impact the findings.

In the bench test, attenuation of NDMA was not consistently observed. NDMA exhibited both increases and decreases in the effluent samples in the bench test. The difference in observations could be that exposure to the atmosphere was minimized in the bench test hence limiting removal by volatilization. In the pilot study, conditions allowed for exposure to the atmosphere.

Although it is suspected that there is some attenuation of NDMA caused by volatilization, NDMA could still present a potential threat to groundwater.

Summary of Median [Minimum - Maximum] Data for N-Nitroso Dimethylamine (NDMA) (ng/L)

4.1.4.5. Terbuthylazine

Terbuthylazine was detected only once in the recycled water during the course of the pilot study, at the reporting limit of 0.1 µg/L. After the baseline sampling event, terbuthylazine was monitored only in the recycled water source because continued monitoring in the subsurface would not yield useful data for a constituent that is detected infrequently. In the bench test, terbuthylazine was not detected in the influent or effluent samples. Because terbuthylazine is not prominent in the recycled water source, the attenuation behavior was not observed.

Summary of Median [Minimum - Maximum] Data for Terbuthylazine (µg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	ND 0.1 [ND 0.1 - 0.1]	-	-	ND 0.1 [ND 0.1 - ND 0.1]
Sample Events		-	-	-
Mann-Kendall Trend	None	-	-	-

4.1.4.6. Perfluorochemicals (PFCs)

The three PFCs monitored in the pilot study were perfluorobutanoic acid (PFBA), perfluorooctanesulfonate (PFOS), and perfluorooctonoic acid (PFOA). PFOS and PFOA were consistently observed to be highest in the recycled water compared to the subsurface samples. One sample collected directly from SJ/SC WPCP did not detect PFCs. PFCs were consistently detected in the recycled water at the pilot study site. In the subsurface samples for the pilot study, PFOS was detected sporadically in the lysimeters and the groundwater at low concentrations. PFOA appeared more consistently in L5-COMP and sporadically in the L10-COMP and the groundwater. With respect to depth, PFOS and PFOA concentrations were significantly lower at the five foot depth compared to the recycled water. Concentrations of PFOS and PFOA were not significantly different between the lysimeters and groundwater. Although no clear trend over time was observed for PFOS or PFOA in the subsurface samples, their presence in the subsurface suggests the potential to migrate to groundwater. In the bench test, PFBA and PFOS were consistently below detection in the SJ/SC WPCP source sample, but were observed in the effluent of one of the soil cores. PFOA was detected in the SJ/SC source samples, but was observed at higher concentrations in the effluent of all of the soil cores irrigated with recycled water. These concentration increases during the bench test were attributed to PFC formation from chemical precursors.

In the pilot study, PFBA was detected only once in the recycled water source, but was detected frequently in the pore water at five feet and once in the pore water at ten feet. PFBA was not detected in groundwater throughout the pilot study. PFBA showed a statistically significant downward trend over time in L5-COMP. The appearance of PFBA in the pore water may be the result of transformation from chemical precursors, which include various fluorinated alcohols and other fluorochemicals. Overall, detections of PFCs in subsurface samples suggest that there is some potential for PFCs in recycled water to impact groundwater.

The baseline event for this study did not detect PFCs in the groundwater at the site. The PFCs in the shallow pore water could not have originated from Coyote Creek, because there is no lateral movement through the vadose zone, and the elevation of the pore water samples (5 feet and 10 feet below ground surface) is above the water level in Coyote Creek.

The only data qualifier flag that was applied to the PFC results in the pilot study was the "D" flag, which affected only results from the IDT source samples in the second and fifth sampling event. A discussion of the "D" flag is found in Section 4.2.4. Although there is some reduced confidence in the quantification of those concentrations, the data appear to be consistent with other samples from the same source, and are still appropriately useful for comparative purposes. Therefore, they are still used for evaluation in this study.

Summary of Median [Minimum - Maximum] Data for Perfluorochemicals (PFBA) (ng/L)

4.1.4.7. NTA and EDTA

Nitrilotriacetic acid (NTA) and ethylenediaminetetraacetic acid (EDTA) were not detected in any samples during the pilot study. The reporting limit for each constituent was 100 µg/L. After the second sampling event, NTA monitoring was discontinued, and EDTA monitoring was conducted only for the recycled water source. In the bench test, NTA was also consistently below detection in both influent and effluent samples. In the bench test, EDTA exhibited increases and decreases in concentration in the effluent compared to the influent. Due to the lack of detection of NTA in the recycled water in the pilot study, the attenuation behavior could not be observed. For EDTA, detections were not observed in the pilot study and attenuation was not consistently observed in the bench test.

Summary of Median [Minimum - Maximum] Data for Nitrilotriacetic acid (NTA) (µg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater

Mann-Kendall Trend	None - All Ties	-	-	-

4.1.4.8. Surfactants

During the pilot study, surfactants were detected only once in the recycled water source, during the baseline sampling event. After the second sampling event, monitoring of surfactants was conducted only for the recycled water source. The reporting limit was 0.2 µg/L for surfactants. Additional surfactants from the AquatrolsSisteen 90 additive contributed to surfactants on the surface. However, there were no detections in L5-COMP in the two events that it was monitored. Attenuation behavior in the pilot study could not be observed, since detection of this constituent was infrequent.

In the bench test, surfactants exhibited increases and decreases in the effluent samples compared to the influent samples. From the results in the bench test, the attenuation of surfactants was not consistently observed.

Summary of Median [Minimum - Maximum] Data for Surfactants (MBAS) (mg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	ND 0.2 [ND 0.2 - 0.21]	-	-	ND 0.1 [ND 0.1 - ND 0.1]
Sample Events		ND 0.2 [ND 0.2 - ND 0.2]	ND 0.2 [ND 0.2 - ND 0.2]	ND 0.2 [ND 0.2 - ND 0.2]
Mann-Kendall Trend	None - All Ties	-	-	-

4.1.4.9. Perchlorate

Perchlorate was not detected in two samples of recycled water collected for the baseline and first sampling events. After the first sampling event, perchlorate was removed from the monitoring program due to the lack of detection in the recycled water source. Perchlorate was detected in one of the monitoring wells during the baseline sampling event, but since that concentration was observed prior to recycled water application, it is not considered relevant to this study. Similarly, perchlorate was not detected in the influent or effluent samples in the bench test. The reporting limit was 4 µg/L for perchlorate. Because perchlorate is not prominent in the recycled water source, the attenuation behavior was not observed, however the lack of detection suggests that perchlorate does not pose a concern for groundwater impacts due to recycled water irrigation.

Summary of Median [Minimum - Maximum] Data for Perchlorate (µg/L)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	ND 4 [ND 4 - ND 4]	-	-	ND 4 [ND 4 - 4.3]
Sample Events		-	-	-
Mann-Kendall Trend	-	-	-	-

4.1.5. Pathogens

Pathogens were evaluated by observing bacteria and indicator organisms. Specific parameters observed were heterotrophic bacteria by heterotrophic plate count (HPC), fecal coliforms, total coliform, and E. coli. All of these parameters were observed in recycled water at some point during the pilot study.

Bacteria by HPC, total coliforms, and fecal coliforms were also detected in pore water samples. In groundwater, only HPC and total coliforms were observed. Overall, attenuation of bacteria and indicator organisms were not well observed in the pilot study.

Detectable levels of HPC were consistently observed across the soil depth. Generally, HPC levels did not exhibit a clear trend with respect to depth. On some occasions, bacterial growth in recycled water measured by HPC was shown to be several orders of magnitude higher than the reporting limit. These changes in HPC in the recycled water source did not appear to correlate to any changes in the subsurface samples. In pore water and groundwater, HPC showed some fluctuation over time, but did not show any trend over time. In the bench test, major bacterial growth, as indicated by HPC, was observed in the influent and effluent samples.

Data qualifier flags that were encountered in the HPC results in the pilot study include the "D" and "T" flags, both of which were applied only to samples from the eighth sampling event. A discussion of the flags is found in Section 4.2.4. Although there is some reduced confidence in the quantification of those HPC results, the data are still appropriately useful for comparative purposes and are therefore used for evaluation in this study. None of the above findings for HPC are dependent on observed concentrations in the eighth sampling event.

Summary of Median [Minimum - Maximum] Data for Heterotrophic Plate Count (CFU/ 1mL)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	6300 [<1 D - >57000]	-	-	646 [65 - 2000]
Sample Events		3650 [560 - 10000]	2150 [300 - 3400]	1550 [220 - 11000]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

Total coliform detection was most prominent at L5-COMP although detection was inconsistent. Total coliforms were found sporadically at all locations. The frequency of relatively high levels of total coliforms in the subsurface samples appears to correlate to the winter season when rainwater becomes the primary irrigation source. Because rainwater is not a chlorinated source, bacteria is allowed to grow. During winter 2009/2010, there appears to be an increased frequency of elevated total coliform values compared to winter 2008/2009. Continued monitoring through additional seasons would be needed to determine whether the increasing total coliform values are related to the application of recycled water. Daily samples of total coliform taken at the SJ/SC plant in 2009 ranged from less then 1 to 5 CFU/100mL.

Summary of Median [Minimum - Maximum] Data for Coliforms, Total (MPN/ 100 mL)				
	Recycled Water	Pore Water (5ft bgs)	Pore Water (10ft bgs)	Groundwater
Baseline	18 [ND 2 - 24]	-	-	1 [ND 2 - 11]
Sample Events		2 [ND 2 - 240]	1 [ND 2 - 81]	ND 2 [ND 2 - 140]
Mann-Kendall Trend	None	None	None	MW-1: None MW-2: None MW-3: None MW-4: None

Fecal coliforms were found at highest levels in the recycled water, however detection was not consistent. Lower detections of fecal coliforms appeared in the pore water during two monitoring events. However, there is no clear trend in these concentrations over time. Fecal coliforms were not observed in the groundwater. E. coli was detected only once in the recycled water. E. coli was not detected in the pore water or groundwater during the pilot study. Overall, there is some evidence suggesting that pathogens in recycled water (particularly as indicated by total coliforms) could have the potential to impact groundwater. However, contributions of coliforms and other indicator bacteria from rain water and from the nearby creek were not evaluated.

Summary of Median [Minimum - Maximum] Data for Fecal Coliforms (MPN/ 100 mL)

4.2. Quality Assurance/Quality Control

Field QA/QC samples were collected to assess the potential for contamination associated with field sampling equipment, containers, and procedures. The field QC samples that were collected are discussed in the following subsections. Although some data collected for this pilot study were qualified as discussed below, after evaluation with respect to the specific conclusions drawn, it was determined that these qualifications do not substantially affect the interpretation or conclusions derived from the data.

4.2.1. Field Duplicates

Duplicate samples were submitted "blind" to the laboratory using a numeric identification and were analyzed for the same parameters as those specified for the primary sample. Results of duplicate samples are presented in Table III-4-3. Primary sample results associated with the field duplicate are also included in the Table III-4-3 for comparison. One field duplicate was collected for every 20 samples. Field duplicates are marked with an "FD". Duplicate samples of the recycled water source (IDT source) were collected in four sampling events throughout the pilot study and in the baseline event. The majority of the duplicate samples were found to be within reasonable range of the project sample, indicating reliability in the laboratory analysis methods for the pilot study. Issues with field duplicates occurred with HPC (one sample in the eighth sampling event), NDMA (one sample in the fifth sampling event) and PFCs (one sample each in the second and fifth sampling event). In cases where the duplicate sample was out of range (relative percent difference (RPD) > 25% to the primary sample), a "D" flag was associated with the project sample result in Table III-4-1.

The RPD exceedance for HPC was 102 percent for the sample from the IDT source in the eighth sampling event. Because of the biological nature of the HPC analysis, results for HPC can vary significantly compared to other analyses. Although there is a reduced confidence in the quantification of this result, the data are still appropriately useful for comparative purposes because HPC variability within this range is not generally considered significant.

The RPD exceedance for NDMA was 37 percent for the sample from the IDT source in the fifth sampling event. This exceedance occurred only once out of the four sampling events that included field duplicates. Although there is some reduced confidence in the quantification of this result, the qualified value is consistent with other concentrations from the IDT source. Additionally, the findings for NDMA are based on concentration differences exceeding 37 percent (see Section 4.1.4.4). Therefore the uncertainty associated with this data qualification does not impact the NDMA findings.

For PFCs, the RPD exceedance for PFOS was 41 percent in the second sampling event and 26 percent in the fifth sampling event. The RPD exceedance for PFOA was 41 percent in the second sampling event. These RPD exceedances applied only to the IDT source samples. There were no RPD exceedances for PFBA. This type of exceedance occurred in two out of the four sampling events with field duplicates. Although there is a reduced confidence in the quantification of these concentrations, the findings of the study regarding PFCs rely primarily on the frequency and locations of detection rather than the quantified concentrations (see Section 4.1.4.6). Therefore the potential for inaccurate quantification of these concentrations does not substantially impact the findings.

4.2.2. Trip Blanks

Trip blanks are used to assess potential cross-contamination of constituents among samples. One trip blank accompanied every 20 samples. The trip blanks consisted of containers filled with deionized water. Results of trip blanks are also presented in Table III-4-3. Trip blanks were collected in four sampling events throughout the pilot study. The majority of the trip blank samples were found below detection, indicating reliability in the sample delivery. Trip blanks with detections occurred with HPC, sodium, alkalinity, and DOC. A detection in the trip blank does not necessarily indicate an issue of quality. If the associated sample results are greater than the concentration detected in the trip blank, the detection in the trip blank would have no effect on the sample results. In instances where the trip blank sample caused an issue of quality, a "T" flag was placed with the associated sample results in Table III-4-1.

For both sodium and alkalinity the concentrations in the trip blanks were much lower than concentrations of the primary samples, such that the primary samples would not be affected. Hence, "T" flags were not assigned to any samples from these constituents.

For DOC, a "T" flag was not assigned to any DOC results from that event because there were no quantifiable results that were below were that had a lower concentration than the trip blank result. For HPC, a "T" flag was assigned to only the HPC result from MW-4 from the eighth sampling event. Although there is some reduced confidence in the quantification of these concentrations, the data are still relevant and used in the study for evaluation purposes.

4.2.3. Rinseate Blanks

A rinseate blank was collected to assess the quality of field decontamination procedures particularly with respect to volatile organic carbons (VOCs). This sample was submitted "blind". No detection was reported for this sample, indicating proper field decontamination procedures.

4.2.4. Flags

Below is a discussion of the different data qualifier flags that have appeared in the pilot study analytical data and any implications for the qualified data. Implications of these flags on the findings are discussed with the analytical results in Section 4.1.

4.2.4.1. "B"

The "B" flag is defined as a low recovery in the matrix spike (MS) and matrix spike duplicate (MSD). The associated relative percent difference (RPD) is out of laboratory limits. The purpose of the MS and MSD is to identify method performance and precision. This flag was applied once for the dissolved organic carbon analysis of L5-COMP in the sixth sampling event.

4.2.4.2. "BB"

The "BB" flag is defined as detection in the associated method blank at or above the laboratory minimum reporting limit (MRL). There is no impact on the reported result due to the "BB" flag because the target analyte is ten times above the concentration level of the detection found in the method blank.

This flag was applied once for the NDMA result in the IDT source sample in the second sampling event which is also qualified with "BD" and "L3" flags.

4.2.4.3. "BD" and "L3"

The "BD" flag is defined as detection in the associated method blank that is above the California Department of Public Health (CDPH) recommended value of 0.5 and does not meet the internal blank limit of one third the MRL. One third of the MRL for NDMA is 0.7 ng/L.

The "L3" flag indicates that the associated blank spike recovery was above the method acceptance limits. A blank spike identifies the performance of the preparation method on a clean matrix that is void of interferences.

Flags "BD" and "L3" were applied to the NDMA result in the IDT source and monitoring well samples in the second sampling event. The monitoring well results are not affected by these qualifiers because

NDMA was not detected in those samples. These flags may indicate potential uncertainty in the quantification of NDMA in the IDT source sample. However, the result is consistent with the other samples collected from that source and is therefore still considered representative.

4.2.4.4. "D"

The "D" flag indicates that the associated field duplicate sample was out of RPD limits with respect to the primary sample. See Section 4.2.1 for discussion of the field duplicates.

4.2.4.5. "J"

The "J" flag indicates that the constituent is detected but the quantitation is an estimate between the method detection limit and the laboratory reporting limit. Estimated values in this range are at a lower confidence than quantitations at or above the reporting limit.

"J" flags were applied to the haloacetic acids results in the IDT source, L5-COMP, and L10-COMP in the sixth through eighth sampling events, and MW-2 in only the eighth sampling event. A "J" flag was also applied to the bromide result from the L10-COMP location in the first sampling event.

4.2.4.6. "P"

The "P" flag indicates that confirmation criteria were exceeded for the gas chromatography or high-performance liquid chromatography. The RPD was greater than 40% between the two analytical results. All data qualified with the "P" flag were also qualifed with a "J" flag.

The "P" flag was applied to the haloacetic acid results from the IDT source, L5-COMP, and L10-COMP locations in the last two sampling events.

4.2.4.7. "R4"

The "R4" flag indicates that the RPD associated with the MS/MSD exceeded method limits, which is similar to the "B" flag. The purpose of the MS and MSD is to identify method performance and precision.

The "R4" flag was applied to the NDMA result for MW-2 in the sixth sampling event. Since this result was below detection, the quantification of this result is not critical to the findings of the study.

4.2.4.8. "S7"

The "S7" flag indicates that the surrogate recovery was below laboratory and method acceptance limits. The effect to the matrix could not be confirmed. The purpose of surrogate recovery is to demonstrate correct sample preparation and absence of matrix effects in the test method.

The "S7" flag was applied to the NDMA result from the L10-COMP location in the seventh sampling event. Since this result was below detection, the quantification of this result is not critical to the findings of the study.

4.2.4.9. "T"

The "T" flag indicates that there is a detection found in the associated trip blank at a concentration greater than the associated sample. See Section 4.2.2 for discussion on the trip blanks.

4.3. Water Budget of Recycled Water to Vadose Zone

A water budget is included in the pilot study evaluation to estimate the amount of water that may infiltrate the soil. The major finding was that for conservative constituents, concentrations of recycled water were estimated to increase by a factor of two in the vadose zone based on the gains and losses of water alone. This estimate is obtained by using a basic hydrologic budget to estimate of the dilution or concentration of recycled water in the vadose zone. An equation for the hydrologic budget is given by:

$F = Bi - Bo + P - ET - S - R$ Brutsaert, 2005

Where
F = Infiltration rate.
Bi = Boundary in condition. For this case, the irrigation rate is used here.
Bo = Boundary out condition, assumed zero.
P = Precipitation.
ET = Evapotranspiration.
S = Storage, assumed negligible.
R = Surface runoff, assumed negligible.

Storage and surface runoff are taken to be negligible. Precipitation, P, in the central San Jose region was reported at 10.04 inches/year for the 2008/2009 winter season (SCVWD, 2009) and 15.12 inches/year for the 2009/2010 winter season (SCVWD, 2010). The average precipitation from the two seasons is 12.58 inches/year. Irrigation application, Bi, at the IDT site was estimated to be 8,717 ccf / year, or 38.7 inches / year (Pacific Crest Engineering Inc., 2005). ET is calculated using

$ET = Kc \times ETo$ University of California Cooperative Extension, 2000

Where
ET = Crop evapotranspiration.
Kc = Crop coefficient.
ETo = Reference evapotranspiration

Kc of warm season turfgrass is 0.6 (University of California Cooperative Extension, 2000). Warm season turfgrass was assumed for the entire irrigated IDT landscape including shrub beds. ETo in the San Jose region is 49.4 inch / year (CIMIS, 1999). Therefore, ET is calculated to be 29.6 inch / year.

Infiltration rate, F, is calculated from the hydrologic budget to be 21.7 inch / year (or 11.2 acre-ft/year). The concentration of recycled water in the vadose zone is estimated to be roughly a factor of 2. This estimate is obtained by using the ratio of the irrigation application rate (38.7 inches/year) to the infiltration rate (21.7 inches/year). TDS data which is taken to be a relatively conservative parameter, supports this estimate. The TDS concentrations in the pore water at five feet bgs is approximately twice that of the recycled water source concentration.

4.4. Piper Diagram Analysis

Piper diagrams graphically summarize cation and anion data in a composite diamond to visually distinguish differences in ionic water quality. In Figure III-4-49, anions including chloride, sulfate, bicarbonate, and cations including calcium, magnesium, sodium, potassium, are plotted as a percent composition of the anions or cations. Compositions are in terms of percentages of equivalence per volume concentrations.

Points for the baseline and sampling events are plotted out. Groundwater data points are an average of the four monitoring wells. L5-COMP and L10-COMP are plotted individually. Recycled water is plotted as one data point, an average of the water quality of the baseline and sampling events through the pilot study since this source is not expected to vary significantly over time.

Of the cations used in the piper diagram, calcium and magnesium appear to be more dominant in groundwater while sodium and/or potassium appear to be more dominant in the recycled water. For the anions, bicarbonate is the dominant anion in groundwater while recycled water is more dominated by chloride.

Comparing the water composition in the recycled water, groundwater, and the pore water, the diagram shows at shallower depths, the water quality is closer to that of recycled water. Visually, L5-COMP data points are more closely plotted to the recycled water while groundwater tends to be plotted furthest away from recycled water.

Over time, trends of the ionic composition in the pore water and the groundwater tend to show a shift towards the ionic composition of recycled water. This is most evident in L5-COMP which is the shallowest depth; however some shift towards an ion composition in recycled water can be discerned in the groundwater data as well.

Trends identified from the piper diagram analysis indicate that recycled water has contributed to the changes in groundwater within the pilot study period. This agrees with other findings of this study, such as NDMA detections observed in the groundwater.

4.5. Conclusions

4.5.1. Constituent Attenuation

Below is a table summarizing the potential threat to groundwater with respect to each constituent based on findings from the pilot study and bench test. Each constituent is given a rating between 1 and 5, with 5 representing the highest potential threat. The criteria for assigning each threat are the observed attenuation of the constituent in the pilot study and bench test and the type of constituent. In general, the greater the overall attenuation behavior displayed from the bench test and pilot study the lower the potential threat. Also considered is whether the constituent is naturally occurring or has known health impacts. The type of constituent can range from general water quality parameters like alkalinity and DO, to emerging contaminants like NDMA and PFCs. The potential threat assigned for each constituent below includes consideration of these factors. Some monitored constituents were not consistently detected in the recycled water source during the study. Since the attenuation of those constituents could not be evaluated, they are assigned as inconclusive. Further monitoring of recycled water sources is needed to determine whether those constituents are sufficiently present to pose a potential threat to groundwater.

In addition to the potential threat value, the table includes a recommendation on whether further monitoring of each constituent is warranted. Constituents that are recommended for further monitoring are those with a threat value of three or higher or if the constituent has been assigned as inconclusive.

Constituent	**Potential Threat**	**Recommend for Further Monitoring?**	**Findings**
ORP	1	N	ORP is a general water quality parameter. Measurements of ORP suggest no major shifts in redox conditions.
pH	1	N	The pH is a general water quality parameter. The pH was near neutral in the pilot study and bench test. Similarity of pH across depth indicates conditions are stable.
Chlorine, Total	1	N	Concentrations of chlorine were higher in groundwater than in recycled water and pore water in the pilot study.
Dissolved Oxygen	1	N	DO is a general water quality parameter. DO was 0.01 mg/L or above across depth in the pilot study indicating that anoxic conditions are unlikely. Samples from the bench test indicated oxic conditions.
Alkalinity, Total	1	N	Alkalinity is a general water quality parameter. A greater alkalinity in the pore water equates to more stability in pH conditions.
Bicarbonate Alkalinity	1	N	
Boron	3	Y	Boron removal was not well observed in the bench test or pilot study.

Calcium	2	Y (See SAR)	Calcium concentrations are greater in the subsurface than in recycled water.
Magnesium	2	Y (See SAR)	Magnesium concentrations are greater in the subsurface than in recycled water.
Sodium	4	Y	Sodium is directly related to SAR, as well as having a direct potential effect on groundwater.
Sodium Adsorption Ratio (SAR)	4	Y	SAR may indicate impact to soil drainage from clay swelling as a result of recycled water application when the SAR in the recycled water is higher than the SAR of the previous irrigation source.
Potassium	1	N	Potassium data from bench test and pilot study suggest good removal.
Sulfate	3	Y	Sulfate increased in concentration in pore water, likely due to contribution from soil and fertilizer. Sulfate concentration in groundwater was relatively stable in the pilot study. In the bench test, removal was not well observed. The constituent also contributes to the total dissolved solids.
Nitrite	2	N	Nitrate/Nitrite data show removal with depth in the pilot study. Mechanism is suspected to be attenuation by root uptake pathway.
Nitrate	2	N	
Chloride	4	Y	Chloride over time has shown an increasing trend in concentrations in groundwater and pore water. At the end of the pilot study, chloride had not yet reached stable conditions. Attenuation of chloride in the bench test was not well observed. The constituent also contributes to the total dissolved solids.
Total Organic Carbon (TOC)	2	N	TOC was decreased by microbial activity and adsorption to soil; groundwater was relatively stable in pilot study. The bench test findings were consistent with the pilot study.
Total Filterable Residue at 180C (TDS)	3	Y	Although TDS in the pilot study in groundwater appeared relatively stable, levels have been observed above secondary drinking water standards in both the baseline and subsequent events. TDS in recycled water and lysimeters are also above secondary drinking water standards. In the bench test, attenuation was not well observed.
Dissolved Organic Carbon	2	N	DOC was decreased by microbial activity and adsorption to soil; groundwater was relatively stable in pilot study. The bench test findings were consistent with the pilot study.

Bromodichloromethane (THM)	2	N	Bromodichloromethane was removed in the vadose zone. Bromodichloromethane was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.
Bromoform (THM)	2	N	Bromoform was removed in the vadose zone. Bromoform was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.
Chloroform (THM)	2	N	Chloroform was removed in the vadose zone. Chloroform was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.
Dibromochloromethane (THM)	2	N	Dibromochloromethane was removed in the vadose zone. Dibromochloromethane was not detected in groundwater during the pilot study. THM data in the bench test also showed attenuative behavior.
Carbon Tetrachloride (VOC)	1	N	Carbon tetrachloride was not detected in recycled water in pilot study or bench test. The constituent was also categorized as having minimal potential impact in Volume I.
Xylenes, Total (VOC)	1	N	Xylenes were not detected in recycled water in pilot study or bench test. The constituent was also categorized as having minimal potential impact in Volume I.
Additional 8010-list VOCs	1	N	VOCs were not detected in recycled water in the pilot study or bench test. VOCs excluding xylenes and carbon tetrachloride were also not detected in the data analysis of Volume I.
Haloacetic Acids (HAA6): Bromochloroacetic Acid Dibromoacetic Acid Monobromoacetic Acid Monochloroacetic Acid Trichloroacetic Acid	4	Y	HAA6 were not observed in the baseline groundwater samples but were observed in the applied recycled water, pore water, and groundwater during the pilot study. In the bench test, HAA6 attenuation was not well observed. HAA6 are also anthropogenic compounds.
Heterotrophic Plate Count	3	Y	Growth was present in pore water and groundwater. Growth was also observed in the bench test. Attenuation was not observed.
Coliforms, Total	3	Y	Growth was present in pore water and groundwater. Growth was also observed in the bench test. Attenuation was not observed.
Fecal Coliforms	3	Y	Fecal Coliforms were not present in groundwater during the pilot study. In the bench test, fecal coliforms were not frequently detected. Attenuation was not well observed.

E. Coli	Inconclusive	Y	E. Coli was minimally detected in recycled water in the pilot study. In the bench test, E. coli was not frequently detected. Therefore the attenuation behavior could not be examined. The constituent may be present in the other recycled water sources in the study area.
N-Nitroso Dimethylamine (NDMA)	5	Y	NDMA was not observed in the baseline groundwater samples, but was observed in the applied recycled water, pore water, and groundwater during the pilot study. The majority of attenuation of NDMA could potentially be from volatilization in the vadose zone and biotransformation in the soil. In the bench test, NDMA attenuation was not consistently observed. NDMA is an emerging contaminant.
Perfluorochemicals	5	Y	PFCs were not observed in the baseline groundwater samples, but were observed in the applied recycled water, pore water, and groundwater during the pilot study. Similarly, in the bench test, some PFCs were observed in the effluent but not in the influent. There is potential for PFC formation from precursors. PFCs are emerging contaminants.
Phosphate	1	N	Phosphate removal was observed in the pilot study and bench test. Mechanisms that caused removal of phosphates are suspected to be the root uptake pathway and precipitation.
Ethylenediaminetetraacetic acid (EDTA)	3	Y	EDTA was not detected in recycled water in the pilot study. In the bench test attenuation was not consistently observed.
Surfactants (MBAS)	3	Y	Surfactants were minimally detected in recycled water in the pilot study. In the bench test attenuation was not consistently observed.
Bromide	2	Y	Removal of bromide in the vadose zone is low; however the degree of toxicity of bromide is low. Together with chloride, bromide can be a useful tracer for recycled water transport.
Nitrilotriacetic acid (NTA)	Inconclusive	Y	NTA was not detected in the pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.
Perchlorate	Inconclusive	Y	Perchlorate was not detected in recycled water during the pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.

Cyanide	Inconclusive	Y	Cyanide was minimally detected in pilot study or bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.
Terbuthylazine	Inconclusive	Y	Terbuthylazine was minimally detected in recycled water in pilot study and bench test. Therefore the attenuation behavior could not be fully examined. This constituent may be present in the other recycled water sources in the study area.

4.5.2. Potential for Reduction in Soil Drainage Caused by Soil Aquifer Plugging

The pilot study has shown based on SAR data that the potential for soil aquifer plugging from recycled water use exists. SAR data suggest clay swelling to some degree in the first five feet. This was indicated by the difference in compositions of sodium, magnesium, and calcium at different soil depths. SAR in the pore water at five feet bgs was much higher than SAR at ten feet bgs and below. Values of SAR found in L5-COMP in the first event were similar to the SAR values of recycled water. Because recycled water was implemented between the baseline and first sampling event, it is possible that clays at the IDT site expanded during this time although baseline data of the pore water was not available to prove this conclusively. The change in permeability due to the clay swelling could not be quantitatively measured. Comparatively, a switch to recycled water can only contribute to clay swelling when the water source previously used has a lower SAR than recycled water. Typically, groundwater will have a lower SAR value than recycled water, as was the observed condition for the pilot study.

In the bench test, clay swelling occurred in the fine-grained soil cores. This was determined by comparing the core effluent volumes of the fine-grained soil cores with and without gypsum applied. The fine-grained soil cores which had gypsum applied achieved greater percolation than the fine-grained soil cores. The use of gypsum, which was not implemented at the pilot study site, promotes permeability by introducing calcium to the system, hence lowering SAR. However, constituent transport downward is also promoted.

5. CONCLUSIONS

5.1. Limitations of the Pilot Study

This pilot study was designed to directly monitor the effect of recycled water irrigation on groundwater at the IDT site in the southern part of the Santa Clara Subbasin. For the purpose of the entire recycled water study, the data and conclusions from this pilot study will be extrapolated for application to the entire project study area, which includes all of Santa Clara and Llagas Groundwater Subbasins. To use this information appropriately, it is important to note the factors that limit the applicability of this data set. These factors are described below.

5.1.1. Duration and Scale

The pilot study monitoring program covered a period of approximately 18 months from September 2008 to March 2010. It was observed that some recycled water constituents have the potential to impact groundwater within this time frame. However, other constituents that migrate more slowly may still have the potential to impact groundwater, but on a longer time frame. Examination of the pore water concentrations at five feet and ten feet can be used to extrapolate potential impacts to groundwater over a longer time period. For example, constituents that affected pore water at five feet after 18 months could affect groundwater at 30 feet after 108 months. Similar extrapolations could be used to approximate conditions for differing groundwater depths.

5.1.2. Site Characteristics

The selected pilot study site has surface and subsurface characteristics that are similar to many other areas with the project study area. However, there are many other sites within the project study area with substantially different characteristics. At the pilot study site, only one type of soil was represented (silty clay). As observed in previous phases of this study, the soil type has significant influence on the migration of recycled water constituents. Extrapolation of the pilot study conclusions to other soil types can serve as a guideline or framework for specific sites but will require careful consideration of the differences in infiltration rate and sorption characteristics.

Recycled water irrigation and infiltration at the pilot study were in areas of turf grass and trees/shrubs. The effect of the specific type of landscaping on recycled water constituent migration could not be evaluated in the pilot study. Application of recycled water for irrigation of other landscape types may require consideration of varying evapotranspiration and nutrient intake rates. However, it is not expected that the landscaping for proposed recycled water applications in the project study area would be significantly different from the IDT site. Pilot study data would be most applicable to a similar mix of landscape.

As described previously, some soil additives in use at the pilot study site may have affected the assessment of certain constituents (e.g. sulfate, potassium, phosphate). This information was factored into the pilot study findings for those affected constituents. Changes in the application of fertilizer or other soil additives should be considered when trying to use the pilot study conclusions for other sites. This is especially the case if gypsum is being used. Gypsum was not applied at the pilot study site, but has been shown in previous phases of this study to have a significant impact on recycled water constituent migration (see Volume II).

5.1.3. Recycled Water Source

Since the pilot study was conducted at a single location, only one source of recycled water (SJ/SC WPCP) was evaluated. Previous phases of this study have shown significant variability between the four sources of recycled water within the project study area (see Volume I). Differences in the recycled water constituent concentrations should be evaluated when using the pilot study data for other recycled water sources.

5.2. Comparison to Previous Phases of the Study

5.2.1. Soil Attenuation Model

In Volume II of this report, transport of four constituents (m-Xylene, chloroform, NDMA, and bromodichloromethane) was simulated using a one-dimensional vadose zone transport model. These constituents were chosen for the soil attenuation model based on the presence of these constituents in recycled water and the availability of information regarding their chemical transport properties. Results from the pilot study of chloroform, NDMA, and bromodichloromethane agreed well with the model results in clayey soils. Xylenes were not detected in the recycled water in the pilot study, and therefore could not be compared. For the four constituents, the pilot study and the model showed a dramatic decrease to near zero in concentration in the pore water at five feet bgs as compared to the recycled water. At five feet in the pilot study, detection of these constituents was very low. The model at five feet (~1.5 meters) showed concentrations to be near zero.

One noted difference between these methods is that the top boundary conditions of the model begin at the soil surface. Processes that occur before infiltration such as the volatilization from spray irrigation are not captured in the model. In the pilot study, the irrigation system exposed the water to ambient air before reaching the soil. In addition, the model did not capture degradation and/or transformation of constituents.

5.2.2. Bench Test

In the bench test, soil core SJSC-A was derived from the IDT site where the pilot study took place. SJSC-D was also derived from the IDT site and this sample was tested with gypsum applied at the surface. However gypsum was not used during the pilot study. Due to the low infiltration rate of recycled water of SJSC-A, very little effluent water was derived from this sample during the bench test. Therefore, there was insufficient sample volume to complete most of the analyses. The length of SJSC-A was 12 inches and the duration of the test for this sample was 121 days. The initial hydraulic conductivity (which was not exposed to recycled water) of this core was measured to be 4.7×10^{-6} cm/sec. Observed hydraulic conductivity (exposed to recycled water) of the soil core at the end of the bench test was less than 1.06×10^{-6} cm/sec.

In general, the pilot study data fluctuated less than the data from the bench test. In the bench test there was a high variation in the data which was attributed to the shorter time frame and shorter soil length evaluated. These variations were minimized in the pilot study. In contrast to the bench test, the pilot study was evaluated over 35 foot soil depth and over a study period of 18 months.

For the bench test, a 20% difference was used as a general guideline to define a significant change between influent and effluent concentrations. In the pilot study, a percentage difference was not used in evaluating the data. Instead, trend data were evaluated using Mann-Kendall analysis. The Mann-Kendall analysis is a more statistically robust analysis, and the pilot study provided a sufficient volume of data for this analysis. The bench test used the percentage difference approach because it included only two sampling events, which is not enough to complete a Mann-Kendall analysis.

5.3. Summary of Potential Threat to Groundwater

Based on the results obtained from the pilot study and bench test, the constituents that showed the highest potential to impact groundwater were NDMA, HAA6, and PFCs, due to their appearance in groundwater during the pilot study and lack of presence in the groundwater baseline data. Some results of NDMA found in the pore water were above the California notification level NDMA of 10 ng/L. In the bench test, NDMA removal was not consistently observed. PFCs have appeared in the groundwater and were not present in the baseline sampling event. PFBA in particular was not found in the recycled water but was found in the other sample locations suggesting transformation to PFBA from other products. HAA6 is also a concern because of its presence in the pore water and potential to impact groundwater. Removal of HAA6 was also not observed in the bench test.

Sodium, magnesium, and calcium are other constituents in recycled water that may adversely affect groundwater. Sodium, magnesium, and calcium can limit soil drainage through clay swelling and the pilot study has suggested based on SAR data that the clays in the shallow soil were already expanded. Swelling is likely to occur due to recycled water because other water sources, such as drinking water and groundwater typically have lower SAR values. The change in permeability due to the clay expansion at the site could not be quantitatively measured. Although not used at IDT during the pilot study, the use of gypsum promotes permeability by introducing calcium to the system, hence lowering SAR. However, constituent transport downward is also promoted. In the bench test, it was observed that the application of gypsum greatly improved permeability of the soil.

Constituents that indicated some potential to impact groundwater include TDS, boron, sulfate, chloride, and pathogens. Rising concentrations of chloride in the pore water and groundwater over time during the pilot study present a concern for potential long-term impact and chloride removal in the bench test was not well observed. Some biological constituents, specifically heterotrophic bacteria and total coliforms, were found to be present in the recycled water and to some extent in the pore water and groundwater. Overall there is some evidence from the pilot study suggesting that pathogens in recycled water could potentially impact groundwater. TDS results in groundwater, pore water, and recycled water from the pilot study and effluent in the bench test were found to be above the secondary drinking water standard. Moderately high levels of TDS found in groundwater at the IDT site, as seen in the baseline and pilot study, leave less capacity for further increases in TDS due to incoming recycled water used in irrigation. Boron and sulfate data from the pilot study and bench test suggested that attenuation was low. The soil and fertilizer was likely to contribute to sulfate in the pore water than recycled water alone.

Most constituents indicated only minimal potential to impact groundwater, including phosphate, nitrate, nitrite, potassium, TOC, DOC, and THMs. Major nutrients such as phosphate and nitrate/nitrite appear to be greatly reduced from irrigation when vegetation is present and fertilizer is appropriately used. The plant uptake process is a potential pathway for nutrient removal. TOC and DOC were not observed to reach groundwater in the pilot study.

Potassium and THMs in groundwater appeared stable in the pilot study. THMs were not detected in groundwater. Potassium was detected in groundwater but at concentrations similar to baseline levels. In addition bench test data of potassium and THMs exhibited removal in the soil.

Alkalinity, pH, ORP, DO, and chlorine showed recycled water had negligible potential to impact groundwater through recycled water use. The stability of general parameters (pH, ORP and DO) as seen in the pilot study and bench test indicate that there were no major shifts in conditions. Chlorine measurements in groundwater in the pilot study were generally higher than in recycled water.

VOCs (excluding THMs) were not detected consistently in recycled water in either the bench test or the pilot study and did not pose a potential threat to groundwater at the IDT site. In addition, Volume I of this study found that xylenes and carbon tetrachloride were regarded as having D) minimal potential impact. The data analysis of Volume I also did not find detections of any other VOCs in recycled water.

Cyanide, terbuthylazine, NTA, and perchlorate were not detected consistently in recycled water in either the bench test or the pilot study. Detections that did occur were near or at the reporting limit. In groundwater, only perchlorate was detected once. Because these parameters were not frequently present in the recycled water source at IDT, they did not have impacts to the groundwater at the IDT site. However, the attenuation behavior of these constituents could not be well examined.

EDTA and surfactants were detected in recycled water during the bench test, but were found to not attenuate well. EDTA and surfactants were not consistently detected in the recycled water in the pilot study, thus conclusions from the pilot study could not be made.

The evaluation of potential threats presented in this section is based on the 18-month pilot study conducted at the IDT site. Due to the fairly limited monitoring period for this study, it is possible that the arrival of some constituents did not occur within the pilot study duration. As part of an agreement with the SCVWD, IDT is conducting ongoing groundwater monitoring at the site, and those results should be considered along with the findings of this study to guide future efforts.

Turf Fertilizer 30-3-9 with Poly-S® Nitrogen & 2% Iron

GUARANTEED ANALYSIS

Total Nitrogen (N)	30.00%
1.17% Ammonical Nitrogen	
28.83% Urea Nitrogen*	
Available Phosphate (P_2O_5)	3.00%
Soluble Potash (K_2O)	9.00%
Sulfur (S)	5.53%
5.53% Free Sulfur (S)	
Total Iron (Fe)	2.00%

Plant nutrients derived from diammonium phosphate, urea, ferrous oxide, polymer coated sulfur coated urea, and potassium chloride.

Chlorine (Cl) Max. 7.62%

*15.0% slowly available nitrogen from polymer coated sulfur coated urea. **F292**

Information regarding the contents and levels of metals in this product is available on the internet at http://www.regulatory-info-ap.com.

DIRECTIONS FOR USE

Apply only as directed. Use Turf Fertilizer 30-3-9 on actively growing fairways and roughs whenever a high nitrogen feeding with quick initial green-up, controlled-release nitrogen and/or iron are desired.

Rates

LOW:	0.75 lb. N/1,000 sq. ft.
MEDIUM:	0.90 lb. N/1,000 sq. ft.
HIGH:	1.25 lb. N/1,000 sq. ft.

For all applications

- For use on fairways and roughs.
- DO NOT USE ON GREENS.
- Do not apply with a drop-type spreader.
- Apply to dry foliage.
- Water in after application with a minimum of 0.2 inches to help move particles in the turf canopy and to avoid possible staining.
- Do not collect clippings for at least one mowing following application to prevent particle pick-up.

Cool Season Grasses

- Apply at LOW or MEDIUM RATE.
- Apply at HIGH RATE in spring or fall when deeper greening is desired or to correct or prevent iron deficiencies.
- Exception: Apply at LOW RATE in mid-summer when temperatures are above 80°F.

Warm Season Grasses

- Apply at LOW or MEDIUM RATE.
- HIGH RATE may be used to help bring grasses out of dormancy in early spring (such as bermudagrass) or to correct or prevent iron deficiencies.
- Exception: Apply at LOW RATE during mid-summer when temperatures are extreme (90°F or above).

Notice: This product contains the micronutrient iron for extra greening and to help prevent iron deficiency. Iron may stain concrete and other surfaces. Misapplied product to these surfaces should be removed promptly by sweeping or blowing. DO NOT WASH OFF WITH WATER.

STORAGE AND DISPOSAL

Store in a clean, dry place. Reseal opened bag by folding top down and securing. Use only clean, dry spreaders. Do not leave unused product in spreaders.

IMPORTANT: READ BEFORE USE

Read the entire Directions for Use and the Warranty Disclaimer and Limitation of Liability before using this product. If terms are not acceptable, return the unopened product container at once. By using this product, user or Buyer accepts the following Warranty Disclaimer and Limitation of Liability:

WARRANTY DISCLAIMER and LIMITATION of LIABILITY

Manufacturer warrants that this product conforms to the chemical description on the label and is reasonably fit for the purposes stated on the label when used in strict accordance with the directions. Manufacturer makes NO OTHER EXPRESS OR IMPLIED WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Where permissible, it is Manufacturer's intent to LIMIT ANY LIABILITY FOR SPECIAL, CONSEQUENTIAL OR INCIDENTAL ECONOMIC DAMAGES to refund of purchase price or replacement of product, at Buyer's choice. Manufacturer DISCLAIMS ANY LIABILITY FOR COMPENSATORY OR OTHER DAMAGES ARISING OUT OF ANY USE CONTRARY TO LABEL DIRECTIONS. Use contrary to label directions is not permitted.

BEST®

Nitra King® 19-4-4 with 2.2% Iron

DESCRIPTION: A COOL SEASON FERTILIZER WITH 4.0% NITRATE NITROGEN

BENEFITS: BEST® NITRA KING® 19-4-4 with 2.2% Iron

- Is a professional fertilizer containing the proper ratio of nitrogen, phosphate, potash, iron, calcium, and sulfur.
- Contains only enough nitrate nitrogen (4.0%) for quick green-up of turf. Minimizes nitrogen loss from nitrate leaching.
- The high iron (2.2%) formula provides deep green color.
- The iron in NITRA KING® is part of a homogeneous pellet which virtually eliminates the possibility of staining valuable concrete walks, driveways, cart paths, mow strips, etc.

HOMOGENEOUS BEST PELLETS

APPLICATION RATES:

FAll FERTilizer
OCT - NOV-

	Pounds of Actual Nitrogen desired per 1,000 sq.ft.	Pounds of NITRA KING® to apply per 1,000 sq.ft.	Pounds of NITRA KING® to apply per Acre
Turfgrass:	.50	2.6	115
	.75	3.9	175
**Recommended Rate*	1.00*	5.2*	230*
	1.25	6.6	285

PREPLANT: Broadcast 7½ lbs. per 1,000 sq. ft. (325 lbs.per acre).
GROUNDCOVER: Broadcast at 5 lbs. per 1,000 sq.ft. (½ lb. per 100 sq.ft.)
FLOWERING SHRUBS & EVERGREENS: Sprinkle ¼ cup of NITRA KING® evenly around dripline of plant and work into top 1inch of soil.
TREES: Apply ½ lb. per 1 inch of trunk diameter. Distribute evenly under branches out to dripline.

NOTE: Liquid measuring cups are very close in estimating the weight of dry granular fertilizers.
Example: An 8 oz. (1 cup) measuring cup holds approximately 8 oz. of dry granular fertilizer.

PRODUCT COVERAGE:

Based on the Recommended Rate.

ONE 50-LB. BAG COVERS 10,400 SQ.FT.
4 50-LB. BAGS COVER ONE ACRE.

BEST®

Ammonium Sulfate 21-0-0

2 grades available: Soluble Fines and Standard Grade

DESCRIPTION: AN ECONOMICAL SOLUBLE FORM OF QUICK GREENING NITROGEN WITH HIGH SULFUR

BENEFITS: BEST® AMMONIUM SULFATE 21-0-0

Winter
Dec. JAN

- Is a quick acting form of water soluble nitrogen that stimulates vegetative growth and produces deep green color.
- Contains high sulfur (24%) to enhance decomposition of thatch through stimulation of soil micro-organisms, improves color and density of turf. Provides for greater drought tolerance and improved winter hardiness.
- Is a very economical form of nitrogen and sulfur.
- Is a very high quality, screened crystaline material that is not produced as a result of any bi-product manufacturing process.

APPLICATION RATES:

	Pounds of Actual Nitrogen desired per 1,000 sq.ft.	Pounds of 21-0-0 to apply per 1,000 sq.ft.	Pounds of 21-0-0 to apply per Acre	Lbs. of Actual Sulfur Applied per 1,000 sq.ft.
Turfgrass:	.50	2.3	100	.55
	.75	3.5	155	.84

GENERAL INFORMATION

Aquatrols® Sixteen 90 is an economical surfactant and a proven alternative for those interested in a longer-lasting surfactant. Aquatrols Sixteen 90 is proven to remain effective in the soil for up to three months reducing water repellency (the cause of localized dry spots). Unlike some "longer-term" surfactants, Aquatrols Sixteen 90 is effective regardless of turf type, environmental or climatic stress conditions.

Aquatrols Sixteen 90 is easily applied with conventional spray equipment. **It is best to make initial** application early in the season before stress begins.

DIRECTIONS FOR USE

GENERAL TURF

Full Rate Application

Apply Aquatrols Sixteen 90 at 16 fl oz/1000 sq ft (480 ml/100 m^2) in 5 gallons (20 L) of water. Apply a post-treatment syringe cycle to activate. For control beyond 3 months, a subsequent application of 8 fl oz/1000 sq ft (240 ml/100 m^2) in 2 gallons (8L) of water may be required for extended performance through the fall period.

Split Application

Apply Aquatrols Sixteen 90 at 8 fl oz/1000 sq ft (240 ml/100 m^2) in 2 gallons (8L) of water, followed 7-10 days later with a second application at 8 fl oz/1000 sq ft (240 ml/100 m^2). Apply a post-treatment syringe cycle to activate. For control beyond 3 months, a subsequent application of 8 fl oz/1000 sq ft (240 ml/100 m^2) in 2 gallons (8L) of water may be required for extended performance through the fall period.

DO NOT combine Aquatrols Sixteen 90 in the spray tank with pesticides or fertilizers unless prior use has shown the combination physically compatible, effective, non-injurious under local conditions.

For more detailed use information, call 1-800-257-7797.

STORAGE AND DISPOSAL

- Keep container tightly closed. Store in original container only. Keep in a secure and locked storage area. Do not add water to the contents of this container.

- Triple rinse container, empty rinse water into spray or stock tank. Dispose of empty containers in accordance with federal, state, and local law.

PRECAUTIONARY STATEMENTS

- CAUTION: MAY CAUSE EYE IRRITATION. DO NOT GET IN EYES.
- AVOID BREATHING VAPORS OR MISTS.
- AVOID USING PRODUCT IN A MANNER AS TO DIRECTLY, OR THROUGH DRIFT, EXPOSE WORKERS OR OTHER PERSONS.
- ALWAYS CONSULT THE MATERIAL SAFETY DATA SHEET FOR SPECIFIC INSTRUCTIONS.
- APPLICATORS AND OTHER HANDLERS MUST WEAR GOGGLES OR A FACIAL SPLASH SHIELD; CHEMICAL RESISTANT GLOVES, SUCH AS NITRILE RUBBER ≥ 14 MILS OR NEOPRENE RUBBER ≥ 14 MILS; COVERALLS OR LONG SLEEVED SHIRT AND LONG PANTS; SHOES PLUS SOCKS.
- KEEP OUT OF REACH OF CHILDREN.

FIRST AID MEASURES IN CASE OF CONTACT

- EYE CONTACT: DO NOT RUB EYES. Immediately flush eyes with large amounts of water for minutes lifting the lower and upper lids. Seek medical attention if necessary.
- SKIN CONTACT: Remove contaminated clothing and immediately wash affected area with lar amounts of water for at least 5 minutes. If irritation or redness persists, seek medical attention needed.
- IF SWALLOWED: If victim is conscious and able to swallow, quickly give milk or water to dilute. not give sodium bicarbonate, vinegar, or fruit juices. Seek medical attention if necessary. Indu vomiting only upon advice from a physician.
- INHALATION: Move individual to fresh air and check to assure adequate respiration. Seek medi attention if necessary.

IN CASE OF EMERGENCY OR SPILL
Contact CHEMTREC at 1-800-424-9300
International 1-703-527-3887 (call collect)

Applicators and other handlers should wash hands before eating, drinking, chewing gum, using tobac or using the toilet. Remove protective clothing and equipment after handling. Wash the outside gloves before removing. Wash thoroughly and change into clean clothing.

For technical information and Material Safety Data Sheet (MSDS), contact Aquatrols at 1-800-257-7797 or visit our website www.aquatrols.com

CONDITIONS OF SALE
LIMITATION OF LIABILITY AND REMEDIES
AQUATROLS CORPORATION OF AMERICA, INC.

Injury to the crop to which the product is applied may result from the occurrence of extraordinary unusual weather conditions, the failure to follow the label directions or good application practices, all which are beyond the control of the seller. In addition, failure to follow label directions may cause injury other crops, animals, man, or the environment.

This product is to be used and applied according to the label directions by professionals trained in the u of agricultural chemicals.

This material is not intended for use by, nor should be used by, consumers. The seller warrants that th product conforms to the chemical description on the label.

The seller makes no other warranties or representations of any kind, expressed or implied, concerni the product, including no implied warranty of merchantability or fitness for any particular purpose, and such warranty shall be implied by law.

The exclusive remedy against the seller for any cause of action relating to the handling or use of th product is claim for damage, and in no event shall damages or any other recovery of any kind against th seller exceed the price of the product which causes the alleged loss, damage, injury or other claim. Th seller shall not be liable and any and all claims against the seller are waived, for special, indirec incidental or consequential damages or expenses, of any nature including but not limited to, loss profits or income, or any liability incurred by the buyer to any third party in any way arising out of relating to the handling, repackaging from original container or the relabeling by the buyer or user, or us of this product, whether or not based on the seller's negligence, breach of warranty, strict liability in tort any other cause of action.

The seller offers this product and the buyer and user accept it, subject to the foregoing conditions of sa and limitation of warranty, liability and remedies.

Information regarding the contents and levels of metals in this product is available on the internet http://www.aapfco.org/metals.htm.

AQUATROLS PERFORMANCE GUARANTEE

Aquatrols guarantees you will be satisfied with the performance of this product when used as directed, your money back. Simply send proof of purchase and a brief reason for dissatisfaction to Aquatrol 1273 Imperial Way, Paulsboro, NJ 08066, USA.

Nemasys® G for Grub Control

Nemasys® G Benefits include:

- Proven curative control
- No restrictions in use and no re-entry interval
- Natural product safe to applicators, users and the environment.
- No requirements for protective clothing
- No concerns for residue run off

How Nemasys G works

Nemasys G contains live nematodes in their vigorously infective stage. These nematodes attack pest larvae by entering their natural body openings. Once inside, they release symbiotic bacteria that quickly kill the insect. Reproduction inside the insect releases a new generation of hungry infective juveniles which disperse in search of further prey.

Active Ingredients: *Heterorhabditis bacteriophora* & water 90%
Other ingredients: inert carrier..10%
Guaranteed Analysis: Each tray contains a minimum of 250 million Nematodes.

		RECOMMENDED RATES
European Chafer Grub	*Rhizotrogus majalis*	3 billion per acre or (12 trays per acre) (1 tray treats 3600 sq. ft.)
Oriental Beetle Grub	*Exomala orientalis*	1 to 2 billion per acre or (4 to 8 trays per acre) (1 tray treats 5400 sq. ft. to 10,800 sq ft)
Japanese Beetle Grub	*Popillia japonica*	

DIRECTIONS FOR USE

- Use 65 to 130 gallons of water per acre spray solution. (1.5 to 3 gallons per 1000 sq. ft.)
- Remove all filters from the application equipment.
- Ensure ground to be treated is moist. Ideally, irrigate prior to application.
- Irrigate the treated area directly after application, before the area dries, with 1/8 of an inch of water.

BOOM SPRAYER APPLICATION:

- Partly fill tank with cool clean water. Start the agitator and keep running until application is completed.
- In a large bucket of 2.5 gallons water, empty the appropriate number of trays, and mix thoroughly.
- Rinse bucket contents into the tank through its sieve.
- Add required volume of additional water to the tank.
- Apply spray suspension to target site.

ISO 9001 REGISTERED

BECKER UNDERWOOD®
Becker Underwood • 801 Dayton Avenue • P.O. Box 667 • Ames, IA 50010 USA
800-232-5907 • 515-232-5907 • fax 515-232-5961 • www.beckerunderwood.com

BACKPACK SPRAYER APPLICATION:

- Make up stock solution by mixing 1 tray in 3 gallons of water. Agitate the stock solution and dilute as follows:
  -Add 1 gallon of stock solution to 2 gallons in the backpack.
  (3 gallons treats 1200 sq. ft., for 3 bil./ac. rate)
  -Add 3 quarts of stock solution to 2.25 gallons in the backpack.
  (3 gallons treats 1350 sq. ft., for 2 bil./ac. rate)
- Repeat with rest of the stock solution.

FOR OPTIMUM RESULTS:

- Use when most grubs are in the 1st and 2nd instar.

TO AVOID DESICCATION OF THE NEMATODES:

- Avoid direct sunlight and make application during early morning or late afternoon/evening.
- Application during rain is highly desirable.
- Ensure soil is moist prior to application and for at least two weeks after.
- It is very important to irrigate immediately after application to move the nematodes below the thatch layer.
- Soil should be between 54° and 86° F at application.
- Use entire tray at one time (do not sub-divide contents of tray).
- Use nematodes immediately after mixing.
- Agitate nematodes constantly during application.

PRECAUTIONS

- Do not use if past expiry date or incorrectly stored.
- Do not tank mix.
- This product will not control the adult stages of the chafer and beetle grubs.
- Do not attempt to hold or store mix solution overnight.
- Do not exceed 150 psi pump pressure.

STORAGE AND DISPOSAL

- Upon receipt remove outer packaging.
- Store in a refrigerator (41°F) but **do not freeze.**
- Ensure good air circulation around each tray.
- Use before expiry date.
- Disposal: product and packaging waste resulting from the use of this product, or unused, out of date product, may be disposed of on site or at any approved waste disposal facility in accordance with local regulations

CONDITIONS OF SALE AND WARRANTY

Becker Underwood warrants that this product conforms to the description on the label. Use and storage of this product is beyond the control of Becker Underwood or the distributor. BECKER UDNERWOOD OR THE DISTRIBUTOR MAKES NO OTHER EXPRESSED OR IMPLIED WARRANTY OF FITNESS OR MERCHANTABILITY OR ANY OTHER EXPRESSED OR IMPLIED WARRANTY. BUYER'S SOLE REMEDY SHALL BE LIMITED TO, AT BECKER UNDERWOOD'S OPTION, EITHER REPLACEMENT OF DEFECTIVE PRODUCT OR FULL REFUND. In no case shall Becker Underwood or the distributor be liable for consequential, special, or indirect damages resulting from the use or handling of this product. In using this product the Buyer accepts these terms and conditions.

Nemasys® is a registered trademark of Becker Underwood

Material Safety Data Sheet **Date Prepared: March 1, 2005** **Supersedes Date: July 12, 2004**

1. CHEMICAL PRODUCT AND COMPANY DESCRIPTION

AQUATROLS CORP
1273 IMPERIAL WAY
PAULSBORO, NJ 08066
USA

Emergency Phone Numbers: For emergencies involving a spill, leak, fire, exposure or accident, contact CHEMTREC 1-800-424-9300

For Product Information: 1-800-257-7797 or www.aquatrols.com

Chemical Name or Synonym: Non-ionic surfactant, wetting agent.

C.A.S. Number: Proprietary

2. COMPOSITION/INFORMATION ON INGREDIENTS

			Exposure Limits	
Component	**CAS Reg. Number**	**Weight (%)**	**OSHA/PEL**	**ACGIH/TLV**
Non-ionic surfactant	Proprietary*	> 99.5	Not established	Not established
Water	7732-18-5	< 0.5	N/A	N/A
Dioxane	123-91-1	< 0.001		90 mg/m^3
Ethylene Oxide	75-21-8	< 0.001		1.8 mg/ m^3
Propylene Oxide	75-56-9	< 0.001		48 mg/ m^3

* Trade secret as allowed by 29 CFR 1901.1200-48

3. HAZARDS IDENTIFICATION

A. Emergency Overview:

Physical Appearance and Odor: Clear to hazy viscous liquid, slight odor.

Warning Statements: CAUTION: May cause irritation.

B. Potential Health Effects:

Primary Route of Entry: Routes of entry for liquids include eye and skin contact, inhalation and ingestion.

Effects of Overexposure:

Acute Eye:	Slightly irritating. May cause excessive watering, redness, and/or irritation.
Acute Skin:	Low acute dermal toxicity. Slightly irritating. May cause redness.
Acute Inhalation:	Inhalation is not likely. Mists may cause upper respiratory tract irritation.
Acute Ingestion:	Overexposure may cause gastrointestinal irritation, diarrhea, nausea, and vomiting.
Chronic Effects:	This product does not contain any ingredient designated by IARC, NTP, ACGIH or OSHA as probable or suspected human carcinogens.

4. FIRST AID MEASURES

EYE CONTACT: DO NOT RUB EYES. Immediately flush eyes with large amounts of water for 15 minutes lifting the lower and upper lids. Seek medical attention if necessary.

SKIN CONTACT: Remove contaminated clothing and immediately wash affected area with large amounts of water for at least 5 minutes. If irritation or redness persists, seek medical attention as needed.

IF SWALLOWED: If victim is conscious and able to swallow, quickly give milk or water to dilute. Do not give sodium bicarbonate, vinegar, or fruit juices. Seek medical attention if necessary. Induce vomiting only upon advice from a physician.

INHALATION: Move individual to fresh air and check to assure adequate respiration. Seek medical attention if necessary.

Medical Conditions Possibly Aggravated by Exposure: Skin contact may aggravate existing skin conditions.

Notes to Physician: All treatments should be based on observed signs and symptoms of distress in the patient. Consideration should be given to the possibility that overexposure to materials other than this product may have occurred. Treat symptomatically. No specific antidote is available.

5. FIRE FIGHTING MEASURES

FIRE HAZARD DATA:

Flash Point: > 93°C (200°F). Flammability class: WILL BURN. **Method Used:** Pensky-Martens Closed Cup

Flammability Limits (vol/vol%): Lower: Not established **Upper:** Not established

Extinguishing Media:
- Recommended:
  - Small fires – dry chemical, carbon dioxide
  - Large fires – alcohol foam, universal foam, water spray
- Not Recommended:
  - Water jet (frothing possible)

Special Fire Fighting Procedures: Firefighters should wear NIOSH/MSHA approved self-contained breathing apparatus and full protective clothing.

Unusual Fire and Explosion Hazards: Product will burn under fire conditions.

Hazardous Decomposition Materials (Under Fire Conditions): Oxides of carbon.

6. ACCIDENTAL RELEASE MEASURES

Containment of Spill: Follow procedure described below.

Cleanup and Disposal of Spill: Absorb with an inert absorbent. Sweep up and place in an appropriate closed container. Clean up residual material by washing area with water. Collect washings for disposal.

Environmental and Regulatory Reporting: Do not flush to drain. Spills may be reportable to the National Response Center (800-424-8802) and to state and/or local agencies.

7. HANDLING AND STORAGE

Minimum/Maximum Storage Temperature: 15 to 49°C (59 to 120°F)

Handling: Avoid breathing vapors and mists. Avoid direct or prolonged contact with skin and eyes. Ethylene oxide may collect in container head space. Although concentrations are expected to remain below established exposure limits, provide adequate ventilation when accessing or working with open containers and tanks.

Storage: Store in tightly closed containers. Store in an area that is dry, well-ventilated, away from ignition sources, and away from incompatible materials (see Section 10. Stability and Reactivity).

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Introductory Remarks:	These recommendations provide general guidance for handling this product. Because specific work environments and material handling practices vary, safety procedures should be developed for each intended application. While developing safe handling procedures, do not overlook the need to clean equipment and piping systems for maintenance and repairs. Waste resulting from these procedures should be handled in accordance with Section 13: Disposal Considerations. Assistance with selection, use and maintenance of worker protection equipment is generally available from equipment manufacturers
Exposure Guidelines:	No exposure limits were found for this product or any of its' ingredients.
Engineering Controls:	When potential for exposure exists, provide adequate general area dilution/exhaust ventilation.
Respiratory Protection:	When respirators are required, use a suitable NIOSH/MSHA approved equipment based on actual or potential airborne concentrations and in accordance with the appropriate regulatory standards and/or industrial recommendations. Under normal conditions with adequate ventilation, no protection is necessary.
Eye/Face Protection:	Appropriate ANSI Z87 approved equipment should be selected for the particular use intended for this material. An available eyewash station is recommended.
Skin Protection:	Skin contact should be minimized through use of appropriate long-sleeved clothing (i.e., shirts and pants). Consideration must be given both to durability as well as permeation resistance. USDA accepted Nitrile (CFR-20) or neoprene rubber (CFR-21) gloves are recommended
Work Practice Controls	Personal hygiene is an important work practice exposure control measure and the following general measures should be taken when working with or handling this material.

1. Do not store, use, and/or consume food, beverages, tobacco products, or cosmetics in area where this material is stored.
2. Wash hands and face carefully before eating, drinking, using tobacco, applying cosmetics, or using the toilet.
3. Wash exposed skin promptly to remove accidental splashes of contact with this material.

9. PHYSICAL AND CHEMICAL PROPERTIES

Physical and Chemical properties here represent typical properties of this product. Contact the business area using the Product Information phone number in Section 1 for exact specifications.

Physical Appearance:	Clear to hazy viscous liquid
Odor:	Slight odor
pH:	5.0 - 7.5 (2.5% solution)
Specific Gravity:	1.02 – 1.04 g/ml @ 25°C
Water Solubility:	Soluble
Melting Point Range:	-4°C at 760 mmHg
Freezing Point Range:	< 0°C (32°F)
Boiling Point Range:	>150°C at 760 mmHg
Vapor Pressure:	< 0.01 mmHg @ 25°C (77°F)
Vapor Density:	>Air (Air = 1 kg/m^3)
Percent Volatiles:	**Volume %:** < 0.5

10. STABILITY AND REACTIVITY

Chemical Stability:	This material is stable under normal handling and storage conditions described in Section 7.
Conditions to be Avoided:	Heat, open flame and spark
Materials/Chemical to be Avoided:	Strong bases, strong oxidizers, strong reducing agents

The following Hazardous Decomposition Products might be Expected:

Decomposition Type: Thermal	Oxides of carbon
Hazardous Polymerization:	Will not occur:
Avoid the Following to Inhibit Hazardous Polymerization:	N/A

11. TOXICOLOGICAL INFORMATION

The following data is for similar or related products.

Acute Eye Irritation: Eye – eye irritation, rabbit – slightly irritating.

Acute Skin Irritation: Skin – skin irritation, rabbit – slightly irritating.

Acute Dermal Toxicity: No test data found for this product.

Acute Respiratory Irritation: No test data found for this product.

Acute Inhalation Toxicity: No test data found for this product.

Acute Oral Toxicity: LD_{50} = 5500 mg/kg – rat.

Chronic Toxicity: This product does not contain any substances that are considered by OSHA, NTP, IARC or ACGIH to be "probable" or "suspected" human carcinogens.

12. ECOLOGICAL INFORMATION

Ecotoxicity Information:	No data available
Environmental Fate Information:	No data available
Chemical/Physical Information:	No data available

13. DISPOSAL CONSIDERATIONS

Waste Disposal Method: Chemical additions, processing or otherwise altering this material may make the waste management information in this MSDS incomplete, inaccurate or inappropriate. Please be advised that state and local requirements for waste disposal may be more restrictive or different from federal laws and regulations. Consult state and local regulations regarding the proper disposal of this material.

14. TRANSPORTATION INFORMATION

Transportation Status: The listed Transportation Classification does not address regulatory variations due to changes in package size, mode of shipment or other regulatory descriptors.

US Department of Transportation Shipping Name: Not Regulated

15. REGULATORY INFORMATION

Inventory Status:

Inventory	Status
UNITED STATES (TSCA)	Y
CANADA (DSL)	Y
EUROPE (EINECS/ELINCS)	P
AUSTRALIA (AICS)	Y
JAPAN (MITI)	Y
SOUTH KOREA (KECL)	Y

Y: All ingredients are on the inventory.
E: All ingredients are on the inventory or exempt from listing.
P: One or more ingredients fall under the polymer exemption or are on the no longer polymer list. All other ingredients are on the inventory or exempt from listing.
N: Not determined or one or more ingredients are not on the inventory and are not exempt from listing.

FEDERAL REGULATIONS:
Inventory Issues: All functional components of this product are listed on the TSCA inventory.

SARA Title III Hazard Classes:

Fire Hazard	NO
Reactive Hazard	NO
Release of Pressure	NO
Acute Health Hazard	NO
Chronic Health Hazard	NO

OTHER FEDERAL REGULATIONS:
FDA Status: N/A

FIFRA Status: N/A

STATE REGULATIONS: This product contains the following components that are regulated under California Proposition 65:

Ingredient	Cancer List	Reprod. List	No Sig. Risk Lvl. (ug/day)	RPI
Dioxane	Y	N	30	ND
Ethylene Oxide	Y	Y	2	ND
Propylene Oxide	Y	N	3	ND

16. OTHER INFORMATION

National Fire Protection Association Hazard Ratings – NFPA(R):

1 Health Hazard Rating – Slight
1 Flammability Rating -- Slight
0 Reactivity Rating -- Minimal

National Paint and Coating Hazardous Materials Identification System - HMIS(R):

1 Health Hazard Rating -- Slight
1 Flammability Rating – Slight
0 Reactivity Rating -- Minimal

Reason for Revisions: Company location change. This MSDS replaces July 12, 2004, MSDS.

Key Legend Information

ACGIH	American Conference of Governmental Industrial Hygienists
OSHA	Occupational Safety and Health Administration
TLV	Threshold Limit Value
PEL	Permissible Exposure Limit
TWA	Time Weighted Average
STEL	Short-Term Exposure Limit
NTP	National Toxicology Program
IARC	International Agency for Research on Cancer
ND	Not determined

Disclaimer:

While the information and recommendations set forth herein are believed to be accurate, we make no warranty with respect hereto and disclaim all liability from reliance thereon.

DAILY FIELD ACTIVITY LOG

Project Name: IOT
Field Activity: Well Sampling
Weather: clear/sunny

Project No.: 27011-07-4100
Date: 5-19-08
Logged by: H. Castro Jr
Page: 1 of 1

TIME	DAILY ACTIVITIES AND EVENTS
645	Prepped & loaded truck for well Sampling.
740	Arrived onsite. Checked in at main lobby.
755	AT MW-1. Take water level & calibrate meter #512.
845	Sampled MW-1.
950	Sampled MW-2.
1050	Sampled MW-3.
1200	Sampled MW-4.
1215	Pete left site with samples to deliver to office.
1225	Offloaded water into open field west of MW-4.
1245	Left site for office.
1330	Arrived at office to finish paperwork & fill out COC's

DAILY FIELD ACTIVITY LOG

Project Name: ~~FOT~~ SCVWD

Field Activity: Well Sampling

Weather: cool

Project No.: 27011-07-4200

Date: 10-27-08

Logged by: A. Castro Sr

Page: 1 of 1

TIME	DAILY ACTIVITIES AND EVENTS
630	Prepped & loaded truck,
740	Arrived onsite. Checked in at main lobby. Calibrated ultra
	meter #312, Coned off wells.
810	AT MW-3. Take DO reading.
855	Sampled MW-3.
930	AT MW-4. Take DO reading.
1005	Sampled MW-4.
1030	AT MW-2. Take DO reading.
1105	Sampled MW-2.
1130	AT MW-1. Take DO reading.
1210	Sampled MW-1.
1245	Offloaded water in field.
1305	Left site for office.
1345	Arrived at office.

LOCUS TECHNOLOGIES

DAILY FIELD ACTIVITY LOG

Project Name: SCVWD/IDT
Field Activity: Well Sampling
Weather: cold/raining

Project No.: 27011-07-4200
Date: 12-15-08
Logged by: H. Castro Jr
Page: 1 of 1

TIME	DAILY ACTIVITIES AND EVENTS
700	Prepped & loaded truck.
800	Arrived onsite. Checked in at main lobby. Calibrated ultrameter #312.
815	AT MW-3. Take DO reading
845	Sampled MW-3.
910	AT MW-4. Take DO reading.
940	Sampled MW-4.
1025	AT MW-2. Take DO reading.
1115	Sampled MW-2.
1145	AT MW-1. Take DO reading.
1230	Sampled MW-1.
1300	Offloaded water into field.
1320	Left site for office
1340	Arrived at office to store & pack samples & fill out COC's.

DAILY FIELD ACTIVITY LOG

Project Name: SCVWD/IDT
Field Activity: Well Sampling
Weather: Clear

Project No.: 27011-07-4200
Date: 2-2-09
Logged by: A. Castro Jr
Page: 1 of 1

TIME	DAILY ACTIVITIES AND EVENTS
645	Loaded truck, purge equipment & coolers.
745	Arrived onsite, checked in at lobby. Calibrated meter #312.
800	AT MW-3. Take DO Reading & Water level.
835	Sampled MW-3.
855	AT MW-4. Take DO Reading & Water level.
935	Sampled MW-4.
950	AT MW-2. Take DO Reading & Water level.
1025	Sampled MW-2.
1110	AT MW-1. Take DO Reading & Water level.
1155	Sampled MW-1.
1235	Offloaded water into field.
1315	Left site
1345	Arrived at office to store, pack Samples & fill out COCs.

DAILY FIELD ACTIVITY LOG

Project Name: SCVWD RECYCLED WATER STUDY
Field Activity: IDT LYSIMETER SAMPLING
Weather:

Project No.: 27011-07-4200
Date: 3/2/09
Logged by: T. MURPHY
Page: 1 of 1

TIME	DAILY ACTIVITIES AND EVENTS
0730	DEPART MV FOR IDT CAMPUS
0800	ARRIVE AT IDT. CHECK IN WITH SECURITY
0815	BEGIN COLLECTING L-5 COMPOSITE SAMPLE
	L1-5 100 ml
	L2-5 1100 ml
	L3-5 0
	* L4-5 680 ml
	* MORE WATER AVAILABLE HERE. I STOPPED AT 680 ml BECAUSE I HAD ENOUGH FOR ALL ANALYSES.
	ALL LYSIMETERS RECHARGED TO 15" hg.
0915	DEPART IDT. HEADING TO SCVWD LAB.
0930	DELIVER BROMIDE SAMPLE TO SCVWD LAB.
1030	RETURN TO MV OFFICE.

DAILY FIELD ACTIVITY LOG

Project Name: SCVWD/IDT
Field Activity: Well Sampling
Weather: clear

Project No.: 27011-07-4200
Date: 4-28-09
Logged by: H. Castro Jr
Page: 1 of 1

TIME	DAILY ACTIVITIES AND EVENTS
715	Loaded truck, purge equip., tank & coolers.
800	Arrived onsite, checked in at lobby. Calibrated meter.
815	AT MW-1. Take DO reading & water level.
900	Sampled MW-1.
930	AT MW-2. Take DO reading & water level.
1010	Sampled MW-2.
1035	AT MW-4. Take DO reading & water level.
1120	Sampled MW-4.
1140	AT MW-3. Take DO reading & water level.
1220	Sampled MW-3.
1235	Offloaded water into field.
1255	Left site.
1320	Arrived at office to store & pack samples.

Project Name: SCVWD RECYCLED WATER STUDY

Field Activity: IDT LYSIMETER SAMPLING

Weather:

Project No. 27011-07-7000

Date: 5/18/09

Logged by: T. MURPHY

Page 1 of 1

TIME	DAILY ACTIVITIES AND EVENTS
0815	DEPART FOR IDT CAMPUS
0900	CHECK IN WITH SECURITY
	BEGIN COLLECTING COMPOSITE SAMPLE FROM L5 LYSIMETERS.
	L3-5 150ml
	L4-5 425 ml - did not extract all
	L1-5 50 ml
	L2-5 450 ml - did not extract all
	ALL LYSIMETERS, L5's & L10's WERE RECHARGED WITH
	15" hg
1000	DEPART. RETURN TO MV OFFICE.

DAILY FIELD ACTIVITY LOG

Project Name: SCVWD
Field Activity: IOT LYSIMETER SAMPLING
Weather:

Project No.: 27011.07.4200
Date: 10/19/09
Logged by: MURPHY
Page: 1 of 1

TIME	DAILY ACTIVITIES AND EVENTS
0800	ON SITE AT IOT CAMPUS. CHECK IN WITH SECURITY.
	BEGIN COLLECTING COMPOSITE SAMPLES FROM LYSMETERS.
	L3-5 0 ml
	-10 0 ml
	L4-5 80 ml
	-10 0 ml
	L2-5 780 ml
	L2-10 80 ml (didn't take it all)
	L1-5 350 ml
	-10 40 ml (didn't take it all)
0915	FILLING BOTTLES.
	HAVE ENOUGH TO COMPLETE L10 COMP BROMIDE SAMPLE.
	FOR L5 COMP I HAVE ENOUGH FOR HPC, TOTAL & FECAL COLIFORMS,
	E. COLI, NDMA, AND PFC'S. CANNOT FILL ~~TOTAL PHOSPHATE~~
	AND BROMIDE.
	↓ Done on 9/28
	CALL NORMAN.
1010	DEPART FOR SCVWD LAB.

TIME	DAILY ACTIVITIES AND EVENTS
0800	ON SITE AT IDT WITH PETE AUSTIN. PETE HAS DUG DOWN TO THE TOP OF L3-5 TO EXPOSE THE TUBING & FITTINGS. BOTH TEFLON TUBES HAVE BEEN DAMAGED IN THE PROCESS AND WILL NEED TO BE REPLACED.
	L3-5 LYSIMETER WILL NOT HOLD A VACUUM CHARGE EVEN WITH THE PUMP & GAUGE INSTALLED DIRECTLY TO THE LYSIMETER.
	I REPLACED THE TUBES AND FITTINGS. AFTER SPEAKING TO WES, WE FILLED IN THE HOLE.
	PETE WILL REMAIN ON SITE TO READ AND RECHARGE THE REST OF THE LYSIMETERS. ALL WILL BE RECHARGED TO 15" hg REGARDLESS OF RESIDUAL CHARGE.

RE: Recycled Water
Work Order: MRE0508

Enclosed are the results of analyses for samples received by the laboratory on 05/19/08 17:30. If you have any questions concerning this report, please feel free to contact me

Sincerely,

Leticia Reyes

Leticia Reyes
Project Manager

CA ELAP Certificate # 2682

The Chain(s) of Custody, 3 pages, are included and are an integral part of this report.

The report shall not be reproduced except in full, without the written approval of the laboratory. The client, by accepting this report, also agrees not to alter any reports whether in the hard copy or electronic format and to use reasonable efforts to preserve the reports in the form and substance originally provided by TestAmerica

For Volatile Analysis a trip blank is required to be provided. If trip blank results are not included in the report, then either the trip blank was not submitted or requested to be analyzed.

The reported results were obtained in compliance with the 2003 NELAC standards unless otherwise noted.

CERTIFICATE OF ANALYSIS

Client: Locus Technologies
299 Fairchild Drive
Mountain View, CA 94043
Attention: Norman Wong

Phone: (650) 641-8258
Fax: (650) 960-0739

Report Date: 06/16/08 13:58
Received Date: 05/21/08 09:00
Turn Around: Normal

Work Order #: 8052109

Client Project: 27011-07-4100

NELAP #04229CA ELAP#1132 NEVADA #CA211 HAWAII LACSD #10143

The results in this report apply to the samples analyzed in accordance with the Chain of Custody document. Weck Laboratories, Inc. certifies that the test results meet all NELAC requirements unless noted in the case narrative. This analytical report is confidential and is only intended for the use of Weck Laboratories, Inc. and its client. This report contains the Chain of Custody document, which is an integral part of it, and can only be reproduced in full with the authorization of Weck Laboratories, Inc.

Dear Norman Wong :

Enclosed are the results of analyses for samples received 05/21/08 09:00 with the Chain of Custody document. The samples were received in good condition. The samples were received at 3.8 °C and on ice. All analysis met the method criteria except as noted below or in the report with data qualifiers.

Notes and Definitions

Q-08	High bias in the QC sample does not affect sample result since analyte was not detected
O-09	This sample was received with the EPA recommended holding time expired
O-04	This analysis was performed outside the EPA recommended holding time.
B-06	This analyte was found in the method blank, which was possibly contaminated during sample preparation The batch was accepted since this analyte was either not detected or more than 10 times of the blank value for all the samples in the batch
ND	NOT DETECTED at or above the Reporting Limit If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL)
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
% Rec	Percent Recovery
Sub	Subcontracted analysis, original report available upon request
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Any remaining sample(s) will be disposed of one month from the final report date unless other arrangements are made in advance.

An Absence of Total Coliform meets the drinking water standards as established by the California Department of Health Services

The Reporting Limit (RL) is referenced as the Laboratory's Practical Quantitation Limit (PQL) or the Detection Limit for Reporting Purposes (DLR).

All samples collected by Weck Laboratories have been sampled in accordance to laboratory SOP Number MIS002

EMLab P&K

Report for:

Mr. Norman Wong
Locus Technologies
299 Fairchild Dr
Mt View, CA 94043

Regarding: Project: 27011-07-3200; Recycled Water
EML ID: 423730

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 05-22-2008
MPN-Standard Bacteria: 05-27-2008

Project SOPs: MPN-Standard Bacteria (100130)

This coversheet is included with your report in order to comply with AIHA and ISO accreditation requirements.

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

EMLab P&K

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.

**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.

Comments
#241730

Group Comments

Report revised to include BA flag for naphthalene blank contamination in EPA Method 525.2 results.
Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210408)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)

Q5 - Sample received with inadequate chemical preservation, but preserved by the laboratory.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte, but analyte not present in the sample.

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210393)

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte not present in the sample.

Laboratory
QC Summary
#241727

Locus Technologies

QC Ref #429644 - N-Nitroso dimethylamine (NDMA) Analysis Date: 05/29/2008

2805210393 MW-4 Analyzed by: dlo

QC Ref #431678 - 525 Semivolatiles by GC/MS Analysis Date: 06/06/2008

2805210393 MW-4 Analyzed by: jxt

QC Ref #434128 - Perfluorinated compounds Analysis Date: 05/25/2008

The following samples were received from you on **05/21/08**. They have been scheduled for the tests listed beside each sample. If this information is incorrect, please contact your service representative. Thank you for using MWH Laboratories.

Sample#	Sample Id	Matrix	Sample Date	Tests Scheduled
2805210360	MW-2	Water	19-may-2008 09:50:00	@525PLUS @NDMA @PFC EDTASUB NTASUB

Test Acronym Description

Test Acronym	Description
@525PLUS	525 Semivolatiles by GC/MS
@NDMA	N-Nitroso dimethylamine (NDMA)
@PFC	Perfluorinated compounds
EDTASUB	EDTA by Ion Chrom-Subcontract
NTASUB	NTA by Ion Chrom- Subcontract

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210360)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)

Perylene-d12(70-130) out of limit
Result out of limits: @525PLUS SURR5251 in sample 2805210360
E6 - Concentration estimated. Internal standard recoveries did not meet method acceptance criteria.

Test: Benzo(a)pyrene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(b)Fluoranthene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(g,h,i)Perylene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(k)Fluoranthene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di(2-Ethylhexyl)phthalate (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Chrysene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Dibenz(a,h)Anthracene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di-N-octylphthalate (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Indeno(1,2,3,c,d)Pyrene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Methoxychlor (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte not present in the sample.

Test: Permethrin (mixed isomers) (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210405)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)

Perylene-d12(70-130) out of limit
Result out of limits: @525PLUS SURR5251 in sample 2805210405
E6 - Concentration estimated. Internal standard recoveries did not meet method acceptance criteria.

Test: Benzo(a)pyrene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(b)Fluoranthene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(g,h,i)Perylene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(k)Fluoranthene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di(2-Ethylhexyl)phthalate (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Chrysene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Dibenz(a,h)Anthracene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di-N-octylphthalate (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Indeno(1,2,3,c,d)Pyrene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Methoxychlor (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte, but analyte not present in the sample.

Test: Permethrin (mixed isomers) (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210357)

Test: 525 Semivolatiles by GC/MS (EPA 525.2)

E6 - Concentration estimated. Internal standard recoveries did not meet method acceptance criteria.

Test: Benzo(a)pyrene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(b)Fluoranthene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(g,h,i)Perylene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Benzo(k)Fluoranthene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di(2-Ethylhexyl)phthalate (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Chrysene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Dibenz(a,h)Anthracene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Di-N-octylphthalate (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Indeno(1,2,3,c,d)Pyrene (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Methoxychlor (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte not present in the sample.

Test: Permethrin (mixed isomers) (ML/EPA 525.2)

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

Group Comments

Analytical results for EDTA and NTA are submitted by Metrohm-Peak, Inc. Houston, TX

(QC Ref#: 2805210356)

Test: Naphthalene (ML/EPA 525.2)

BA - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL), but analyte not present in the sample.

EMLab P&K

Report for:

Mr. Norman Wong
Locus Technologies
299 Fairchild Dr
Mt View, CA 94043

Regarding: Project: 27011-07-3200; Recycled Water
EML ID: 423730

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 05-22-2008

This coversheet is included with your report in order to comply with AIHA and ISO accreditation requirements.

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.

**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.

The following samples were received from you on **10/28/08**. They have been scheduled for the tests listed beside each sample. If this information is incorrect, please contact your service representative. Thank you for using MWH Laboratories.

Sample#	Sample Id Tests Scheduled	Matrix	Sample Date
2810280278	SOURCE @525PLUS @NDMA @PFC EDTASUB NTASUB	Water	27-oct-2008 11:45:00

Test Acronym Description

Test Acronym	Description
@525PLUS	525 Semivolatiles by GC/MS
@NDMA	N-Nitroso dimethylamine (NDMA)
@PFC	Perfluorinated compounds
EDTASUB	EDTA by Ion Chrom-Subcontract
NTASUB	NTA by Ion Chrom- Subcontract

ACCUTEST Laboratories

Sample Receiving Checklist

Job # C2791

Review Chain of Custody: The Chain of Custody is to be completely and legibly filed out by Client.

☐ Are these regulatory (NPDES) samples? Yes / [✓ No] circle one ☐ Is pH requested? Yes / [✓ No] circle one
☐ Was Client informed that the hold time is 15mins Yes / No circle one If yes, did they consent to continue? ______
☐ Are sample within one-half hold-time? Yes / No circle one If no, was the lab informed? ______
☑ Report to info is complete and legible, including:
 ☑ Type of Deliverable needed ☑ name ☑ address ☑ phone ☑ email ON File
☐ Bill to info is complete and legible, including: ☐ PO# ☐ Credit card ☐ contact ☐ address ☐ phone ☐ email
☑ Contact and/or Project Mgr identified, including: ☑ phone ☑ email
☑ Project name / number ☐ Special requirements? [✓ Yes] / No circle one
☑ Sample IDs / date & ~~time~~ of collection provided? [✓ Yes] / No circle one no time of Sampling listed
☑ Matrix listed and correct? [✓ Yes] / No circle one
☑ Analyses listed are those we do or client has authorized a subcontract? [✓ Yes] / No circle one
☑ Chain is signed / dated by both client and sample custodian? [✓ Yes] / No circle one
☑ TAT requested available? Approved by ELK

Review Coolers:

☑ Samples / Coolers are at 0-6°C? 2.9°C If sampled within 4hrs, then "on ice" is acceptable.
If a cooler is outside the 0-6°C range; note below the bottles in that cooler below.
Note that ANC does NOT accept evidentiary samples. (We do not lock refrigerators)
Shipment Method: walk in
Custody Seals Present: Yes / No circle one Un-broken: Yes / No circle one

Review of Sample Bottles: If you answer no, explain below

☑ IDs / bottle number / Date / ~~Time~~ of bottle labels match CoC?
☑ Sample bottle intact? [✓ Yes] / No circle one
☑ Proper containers and volumes? [✓ Yes] / No circle one
☐ Proper preservatives? Check pH on preserved samples except 1664, 625, 8270, and VOAs and list below. N/A
☐ VOAs received without headspace? Yes / No circle one N/A

Lab#	Client Sample ID	pH Check:	Other Comments / Issues
			6x 250mL polys. N/P

☐ Client informed of irregularities at receiving ☐ Project Mgr needs to contact Client for Issues

Comments: <100mL Sample Volume for C2791-006 (L10 Comp)

CASE NARRATIVE

Laboratory number:	**207210**
Client:	**Locus Technologies**
Project:	**27011-07-4200**
Location:	**Recycled Water Study**
Request Date:	**10/27/08**
Samples Received:	**10/27/08**

This data package contains sample and QC results for seven water samples, requested for the above referenced project on 10/27/08. The samples were received cold and intact.

Volatile Organics by GC/MS (EPA 8260B):
Responses exceeding the instrument's linear range were observed for trichloroethene in the MS/MSD for batch 144378; affected data was qualified with "b". No other analytical problems were encountered.

Metals (EPA 6010B):
No analytical problems were encountered.

Ion Chromatography (EPA 300.0):
No analytical problems were encountered.

Perchlorate by Ion Chromatography (EPA 314.0):
No analytical problems were encountered.

Total Cyanide (SM4500CN-E):
No analytical problems were encountered.

Alkalinity (SM2320B):
No analytical problems were encountered.

Total Dissolved Solids (TDS) (SM2540C):
No analytical problems were encountered.

Total Phosphorous (SM4500P-E):
No analytical problems were encountered.

Total Organic Carbon (TOC) (SM5310C):
No analytical problems were encountered.

Dissolved Organic Carbon (DOC) (SM5310C):
No analytical problems were encountered.

Surfactants (MBAS) (SM5540C):
No analytical problems were encountered.

EPA 552 (EPA 552):
Weck Laboratories, Inc. in Hacienda Heights, CA performed the analysis.

CASE NARRATIVE

COOLER RECEIPT CHECKLIST

ct Curtis & Tompkins, Ltd

Login # 207210 Date Received 10/27/08 Number of coolers 5
Client LOCUS Project Recycled Water Study

Date Opened 10/27 By (print) K Wellbrock (sign) K Wellbrock
Date Logged in ↓ By (print) ↓ (sign) ↓

1. Did cooler come with a shipping slip (airbill, etc)? .... YES [✓ NO]
   Shipping info

2A. Were custody seals present? .... ☒YES (circle) [✓ on cooler] on samples ☐ NO
   How many 1 each Name Tom Murphy Date 10/27/08 1500

2B. Were custody seals intact upon arrival? .... [✓ YES] NO N/A

3. Were custody papers dry and intact when received? .... [✓ YES] NO

4. Were custody papers filled out properly (ink, signed, etc)? .... [✓ YES] NO

5. Is the project identifiable from custody papers? (If so fill out top of form) .... [✓ YES] NO

6. Indicate the packing in cooler: (if other, describe)

☒ Bubble Wrap
☐ Cloth material
☐ Foam blocks
☐ Cardboard
☒ Bags
☐ Styrofoam
☐ None
☐ Paper towels

7. Temperature documentation:

Type of ice used: ☒ Wet ☐ Blue/Gel ☐ None Temp(°C)

☒ Samples Received on ice & cold without a temperature blank

☐ Samples received on ice directly from the field. Cooling process had begun

8. Were Method 5035 sampling containers present? .... YES [✓ NO]
   If YES, what time were they transferred to freezer?

9. Did all bottles arrive unbroken/unopened? ....

10. Are samples in the appropriate containers for indicated tests? .... [✓ YES] NO

11. Are sample labels present, in good condition and complete? .... [✓ YES] NO

12. Do the sample labels agree with custody papers? .... [✓ YES] NO

13. Was sufficient amount of sample sent for tests requested? .... [✓ YES] NO

14. Are the samples appropriately preserved? .... [✓ YES] NO

15. Are bubbles > 6mm absent in VOA samples? .... [✓ YES] NO N/A

16. Was the client contacted concerning this sample delivery? .... YES NO
   If YES, Who was called? By Date:

Certificate of Analysis

Notes:
The Chain of Custody document is part of the analytical report.
Any remaining sample(s) for testing will be disposed of one month from the final report date unless other arrangements are made in advance.
All results are expressed on wet weight basis unless otherwise specified.
ND = NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL).
Sub = Subcontracted analysis, original report enclosed.
Dil = Dilution Factor
MDL = Method Detection Limit
MDA = Minimum Detectable Activity

An Absence of Total Coliform meets the drinking water standards as established by the State of California Department of Health Services.
The Reporting Limit (RL) is referenced as laboratory's Practical Quantitation Limit (PQL).
For Potable water analysis, the Reporting Limit (RL) is referenced as Detection Limit for reporting purposes (DLRs) defined by EPA.

If sample collected by Weck Laboratories, sampled in accordance to lab SOP MIS002

NELAC # 04229CA

The results in this report apply to the samples analyzed in accordance with the chain of custody document. Weck Laboratories certifies that the test results meet all requirements of NELAC unless noted in the Case Narrative. This analytical report must be reproduced in its entirety.

Flags for Data Qualifiers:

MS-02 = The RPD and/or percent recovery for this QC spike sample cannot be accurately calculated due to the high concentration of analyte inherent in the sample.

S-03 = High surrogate recovery for this sample is possibly due to a sample matrix effect. The data was accepted since all target analytes were not detected.

Sample Receiving Checklist

Job # C3141

Review Chain of Custody: The Chain of Custody is to be completely and legibly filed out by Client.

☑ Are these regulatory (NPDES) samples? Yes / [✓ No] circle one ☑ Is pH requested? Yes / [✓ No] circle one
☐ Was Client informed that the hold time is 15mins Yes / No circle one If yes, did they consent to continue? ______
☐ Are sample within one-half hold-time? Yes / No circle one If no, was the lab informed? ______
☑ Report to Info is complete and legible, including;
  ☑ Type of Deliverable needed ☑ name ☑ address ☑ phone ☑ email
☐ Bill to info is complete and legible, including: ☐ PO# ☐ Credit card ☐ contact ☐ address ☐ phone ☐ email
☑ Contact and/or Project Mgr identified, including; ☑ phone ☑ email
☑ Project name / number ☐ Special requirements? [✓ Yes] / No circle one
☑ Sample IDs / date & time of collection provided? [✓ Yes] / No circle one
☑ Matrix listed and correct? [✓ Yes] / No circle one
☑ Analyses listed are those we do or client has authorized a subcontract? [✓ Yes] / No circle one
☑ Chain is signed / dated by both client and sample custodian? [✓ Yes] / No circle one
☑ TAT requested available? Approved by ELK

Review Coolers:
☑ Samples / Coolers are at 0-6°C? 1.6°C If sampled within 4hrs, then "on ice" is acceptable.
If a cooler is outside the 0-6°C range; note below the bottles in that cooler below.
Note that ANC does NOT accept evidentiary samples. (We do not lock refrigerators)
Shipment Method: walk In
Custody Seals Present: Yes / [✓ No] circle one Un-broken: Yes / No circle one

Review of Sample Bottles: If you answer no, explain below
☑ IDs / bottle number / Date / Time of bottle labels match CoC?
☑ Sample bottle intact? [✓ Yes] / No circle one
☑ Proper containers and volumes? [✓ Yes] / No circle one
☐ Proper preservatives? Check pH on preserved samples except 1664, 625, 8270, and VOAs and list below. N/A
☐ VOAs received without headspace? Yes / No circle one N/A

Lab #	Client Sample ID	pH Check:	Other Comments / Issues
			1X 250mL poly N/P

☐ Client informed of irregularities at receiving ☐ Project Mgr needs to contact Client for issues

EMLab P&K

Report for:

Mr. Norman Wong
Locus Technologies
299 Fairchild Dr
Mt View, CA 94043

Regarding: Project: 27011-07-4200
EML ID: 609788

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
MPN-Standard Bacteria: 12-21-2009

Service SOPs: MPN-Standard Bacteria (100130)

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.
**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.
‡ A "Version" indicated by -"x" after the Lab ID# with a value greater than 1 indicates a sample with amended data. The revision number is reflected by the value of "x".

Mt View, CA 94043

Regarding: Project: 27011-07-4200; Recycled Water Study
EML ID: 497309

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 12-18-2008
MPN-Standard Bacteria: 12-22-2008

Project SOPs: MPN-Standard Bacteria (100130)

This coversheet is included with your report in order to comply with AIHA and ISO accreditation requirements.

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Flags Legend:

BB - Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL). No major impact on the reported result since the target analyte is = 10x the concentration level.

BD - Target analyte detected in method blank is above CA DHS recommended value of 0.5 and did not meet the internal blank limit of 1/3 MRL. (1/3 of MRL = 0.7)

L3 - The associated blank spike recovery was above method acceptance limits.

Method Blank and LCS contamination resulted in detections in method blank. However, results for all affected samples are Non-Detect and MS, MSD and other QC did meet lab/method acceptance criteria. Therefore, data is acceptable for reporting.

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

CASE NARRATIVE

Laboratory number:	**208644**
Client:	**Locus Technologies**
Project:	**27011-07-4200**
Location:	**Recycled Water Study**
Request Date:	**12/15/08**
Samples Received:	**12/15/08**

This data package contains sample and QC results for nine water samples, requested for the above referenced project on 12/15/08. The samples were received cold and intact.

Volatile Organics by GC/MS (EPA 8260B):
No analytical problems were encountered.

Metals (EPA 6010B):
No analytical problems were encountered.

Ion Chromatography (EPA 300.0):
No analytical problems were encountered.

Total Cyanide (SM4500CN-E):
No analytical problems were encountered.

Alkalinity (SM2320B):
No analytical problems were encountered.

Total Dissolved Solids (TDS) (SM2540C):
No analytical problems were encountered.

Total Phosphorous (SM4500P-E):
No analytical problems were encountered.

Total Organic Carbon (TOC) (SM5310C):
No analytical problems were encountered.

Dissolved Organic Carbon (DOC) (SM5310C):
No analytical problems were encountered.

Surfactants (MBAS) (SM5540C):
No analytical problems were encountered.

EPA 552 (EPA 552):
Weck Laboratories, Inc. in Hacienda Heights, CA performed the analysis. Please see the Weck Laboratories, Inc. case narrative.

COOLER RECEIPT CHECKLIST

Curtis & Tompkins, Ltd.

Login # 208644 Date Received 12/15/8 Number of coolers 4
Client LOCUS Project RECYLED WATER SUPPLY

Date Opened 12/15/8 By (print) S. EVANS (sign)
Date Logged in By (print) (sign)

1. Did cooler come with a shipping slip (airbill, etc) YES [✓ NO]
Shipping info

2A. Were custody seals present? ☒ YES (circle) [✓ on cooler] on samples ☐ NO
How many 1 PER Name Tom M. Date 12/15/08
2B. Were custody seals intact upon arrival? [✓ YES] NO N/A
3. Were custody papers dry and intact when received? [✓ YES] NO
4. Were custody papers filled out properly (ink, signed, etc)? [✓ YES] NO
5. Is the project identifiable from custody papers? (If so fill out top of form) [✓ YES] NO
6. Indicate the packing in cooler: (if other, describe)

☒ Bubble Wrap
☐ Cloth material
☐ Foam blocks
☐ Cardboard
☒ Bags
☐ Styrofoam
☐ None
☐ Paper towels

7. Temperature documentation:

Type of ice used: ☒ Wet ☐ Blue/Gel ☐ None Temp(°C) 4

☐ Samples Received on ice & cold without a temperature blank

☐ Samples received on ice directly from the field. Cooling process had begun

8. Were Method 5035 sampling containers present? YES [✓ NO]
If YES, what time were they transferred to freezer?
9. Did all bottles arrive unbroken/unopened? [✓ YES] NO
10. Are samples in the appropriate containers for indicated tests? [✓ YES] NO
11. Are sample labels present, in good condition and complete? [✓ YES] NO
12. Do the sample labels agree with custody papers? [✓ YES] NO
13. Was sufficient amount of sample sent for tests requested? [✓ YES] NO
14. Are the samples appropriately preserved? [✓ YES] NO N/A
15. Are bubbles > 6mm absent in VOA samples? [✓ YES] NO N/A
16. Was the client contacted concerning this sample delivery? YES NO
If YES, Who was called? By Date:

Anna Pajarillo

From: "Wong, Norman" <Wongn@locustec.com>
To: "Anna M. Pajarillo" <anna@ctberk.com>
Sent: Tuesday, December 16, 2008 11:43 AM
Subject: cancel bromide

Hi Anna,

The courier just picked up some samples yesterday. There is one analyte I want to have canceled on the COC and that is bromide by EPA 300.0. There are other analytes by EPA 300.0 which I want to keep. This project is for the recycled water study.

Norman Wong, Assistant Project Engineer

Notes:
The Chain of Custody document is part of the analytical report.
Any remaining sample(s) for testing will be disposed of one month from the final report date unless other arrangements are made in advance.
All results are expressed on wet weight basis unless otherwise specified.
ND = NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL).
Sub = Subcontracted analysis, original report enclosed.
Dil = Dilution Factor
MDL = Method Detection Limit
MDA = Minimum Detectable Activity

An Absence of Total Coliform meets the drinking water standards as established by the State of California Department of Health Services.
The Reporting Limit (RL) is referenced as laboratory's Practical Quantitation Limit (PQL).
For Potable water analysis, the Reporting Limit (RL) is referenced as Detection Limit for reporting purposes (DLRs) defined by EPA.

If sample collected by Weck Laboratories, sampled in accordance to lab SOP MIS002

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

Bromide	0.17	mg/L		

Legend:

DLR = Detection Limit For Reporting
ND = Not Detected At Or Above The DLR
NT = Not Tested
NR = Not Reported

ABS = Centimeters $^{-1}$
Cells/ml = Cells Per Milliliter
CFU/100 ml = Colony Forming Units Per 100 Milliliters
CFU/ml = Colony Forming Units Per Milliliter
cysts/L = Cysts Per Liter
Deg C = Degrees Centigrade
mg/L = Milligrams Per Liter
MPN/100ml = Most Probable Number Per 100 Milliliters
ng/L = Nanograms Per Liter

NTU = Nephelometric Turbidity Units
oocysts/L = Oocysts Per Liter
P/A 100ml = Presence/Absence Per 100 Milliliters
pCi/L = Picocuries Per Liter
Rhod-Eqiv = Rhodamine Equivalents
T O N = Threshold Odor Number
ug C/L = Micrograms Carbon Per Liter
ug/L = Micrograms Per Liter
umhos= Microhms

Data Qualifier Definitions:

A = Results may be biased high
B = Results may be biased low
D = Analyte is present in method blank

E = Analyte confirmation on secondary column
G = Sample hold time exceeded
H = Presence verified but not quantified
I = Sample unpreserved or improperly preserved

J = Estimated result; value may not be accurate
K = Too numerous to count; value represents filtration volume
L = Matrix interference(s)
M = Field blanks not prepared at customer's request

Report Notes:

QCS, spike recovery, and RPD values that are outside of established limits are underlined.

If an LFM recovery exceeds the established limits for any analyte, and the laboratory performance for other QC parameters is shown to be in control for that analyte, then failure is not system related but due to matrix interferences and is labeled as suspect.

Reported values that are flagged "H" are above the established acceptance range; reported values that are flagged "L" are below the acceptance range. RPD results flagged "H" are above the established RPD limit -

Quality control sample (LFB, LFM, LFM D, QCS, QCS R, and Surrogate) reporting frequency is based on the method requirement (e g . a QCS may not be run with every batch).

Legend:

LFB = Laboratory Fortified Blank: An aliquot of a Laboratroty Reagent Blank (LRB) to which known quantities of the method analytes are added in the laboratory The LFB i analyzed exactly like a sample

LFB D = Laboratory Fortified Blank Duplicate: A duplicate aliquot of an LRB to which known quantities of the method analytes are added in the laboratory The LFB D is analyzed exactly like a sample

LFM = Laboratory Fortified Matrix: An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory The LFM is analyze exactly like a sample

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory The LFM D is analyzed exactly like a sample

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained fron a source external to the laboratory and different from the source of calibration standards Result is weighed against a specified concentration range

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS R i obtained from a source external to the laboratory and different from the source of calibration standards Result is weighed against a specified recovery range

RPD = Relative Percent Difference

SUR = Surrogate An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.

**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.
‡ A "Version" greater than 1 indicates amended data.

CASE NARRATIVE

Laboratory number:	**209687**
Client:	**Locus Technologies**
Project:	**27011-07-4200**
Location:	**Recycled Water Study**
Request Date:	**02/02/09, 02/10/09**
Samples Received:	**02/02/09**

This data package contains sample and QC results for eight water samples, requested for the above referenced project on 02/02/09 and 02/10/09. The samples were received cold and intact.

Volatile Organics by GC/MS (EPA 8260B):
No analytical problems were encountered.

Metals (EPA 6010B):
No analytical problems were encountered.

Ion Chromatography (EPA 300.0):
No analytical problems were encountered.

Total Cyanide (SM4500CN-E):
No analytical problems were encountered.

Alkalinity (SM2320B):
No analytical problems were encountered.

Total Dissolved Solids (TDS) (SM2540C):
No analytical problems were encountered.

Total Phosphorous (SM4500P-E):
No analytical problems were encountered.

Total Organic Carbon (TOC) (SM5310C):
No analytical problems were encountered.

Dissolved Organic Carbon (DOC) (SM5310C):
No analytical problems were encountered.

Surfactants (MBAS) (SM5540C):
No analytical problems were encountered.

EPA 552 (EPA 552):
Weck Laboratories, Inc. in Hacienda Heights, CA performed the analysis. Please see the Weck Laboratories, Inc. case narrative.

Notes:
The Chain of Custody document is part of the analytical report.
Any remaining sample(s) for testing will be disposed of one month from the final report date unless other arrangements are made in advance.
All results are expressed on wet weight basis unless otherwise specified.

An Absence of Total Coliform meets the drinking water standards as established by the State of California Department of Health Services.
The Reporting Limit (RL) is referenced as laboratory's Practical Quantitation Limit (PQL).
For Potable water analysis, the Reporting Limit (RL) is referenced as Detection Limit for reporting purposes (DLRs) defined by EPA.

If sample collected by Weck Laboratories, sampled in accordance to lab SOP MIS002

The results in this report apply to the samples analyzed in accordance with the chain of custody document. Weck Laboratories certifies that the test results meet all requirements of NELAC unless noted in the Case Narrative. This analytical report must be reproduced in its entirety.

Flags for Data Qualifiers:

ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL).
Sub	Subcontracted analysis, original report enclosed.
Dil	Dilution Factor
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Laboratory Comments
Report: #303170

Locus Technologies
Norman Wong
299 Fairchild Drive
Mountain View, CA 94043

Flags Legend:

L3 - The associated blank spike recovery was above method acceptance limits.

Group Comments

PFOS-c13 surrogate recovery was low. However, data is acceptable based on passing LCS and result correction using Isotope Dilution

Semivolatiles (EPA 525.2) data is acceptable based on passing LCS1 and other QC.

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

Laboratory Analyst(s)

James N. Scott

Legend:

DLR = Detection Limit For Reporting
ND = Not Detected At Or Above The DLR
NT = Not Tested
NR = Not Reported

ABS = Centimeters $^{-1}$
Cells/ml = Cells Per Milliliter
CFU/100 ml = Colony Forming Units Per 100 Milliliters
CFU/ml = Colony Forming Units Per Milliliter
cysts/L = Cysts Per Liter
Deg. C = Degrees Centigrade
mg/L = Milligrams Per Liter
MPN/100ml = Most Probable Number Per 100 Milliliters
ng/L = Nanograms Per Liter

NTU = Nephelometric Turbidity Units
oocysts/L = Oocysts Per Liter
P/A 100ml = Presence/Absence Per 100 Milliliters
pCi/L = Picocuries Per Liter
Rhod-Eqiv = Rhodamine Equivalents
T.O.N. = Threshold Odor Number
ug C/L = Micrograms Carbon Per Liter
ug/L = Micrograms Per Liter
umhos= Microhms

Data Qualifier Definitions:

A = Results may be biased high.
B = Results may be biased low.
D = Analyte is present in method blank.

E = Analyte confirmation on secondary column.
G = Sample hold time exceeded.
H = Presence verified but not quantified.
I = Sample unpreserved or improperly preserved.

J = Estimated result; value may not be accurate.
K = Too numerous to count; value represents filtration volume.
L = Matrix interference(s).
M = Field blanks not prepared at customer's request.

Batch: 55392

Report Notes:

QCS, spike recovery, and RPD values that are outside of established limits are underlined.

If an LFM recovery exceeds the established limits for any analyte, and the laboratory performance for other QC parameters is shown to be in control for that analyte, then failure is not system related but due to matrix interferences and is labeled as suspect.

Reported values that are flagged "H" are above the established acceptance range; reported values that are flagged "L" are below the acceptance range. RPD results flagged "H" are above the established RPD limit.-

Quality control sample (LFB, LFM, LFM D, QCS, QCS R, and Surrogate) reporting frequency is based on the method requirement (e.g., a QCS may not be run with every batch).

Legend:

LFB = Laboratory Fortified Blank: An aliquot of a Laboratroty Reagent Blank (LRB) to which known quantities of the method analytes are added in the laboratory. The LFB i analyzed exactly like a sample.

LFB D = Laboratory Fortified Blank Duplicate: A duplicate aliquot of an LRB to which known quantities of the method analytes are added in the laboratory. The LFB D is analyzed exactly like a sample.

LFM = Laboratory Fortified Matrix: An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyze exactly like a sample.

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory The LFM D is analyzed exactly like a sample.

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained fron a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified concentration range.

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS R i obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified recovery range.

RPD = Relative Percent Difference

SUR = Surrogate. An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis.

CASE NARRATIVE

Laboratory number:	**210377**
Client:	**Locus Technologies**
Project:	**27011-07-4200**
Location:	**Recycled Water Study**
Request Date:	**03/02/09**
Samples Received:	**03/02/09**

This data package contains sample and QC results for one water sample, requested for the above referenced project on 03/02/09. The sample was received cold and intact.

Total Phosphorous (SM4500P-E):
No analytical problems were encountered.

EPA 552 (EPA 552):
Weck Laboratories, Inc. in Hacienda Heights, CA performed the analysis. Please see the Weck Laboratories, Inc. case narrative.

Notes:
The Chain of Custody document is part of the analytical report.
Any remaining sample(s) for testing will be disposed of one month from the final report date unless other arrangements are made in advance.
All results are expressed on wet weight basis unless otherwise specified.

An Absence of Total Coliform meets the drinking water standards as established by the State of California Department of Health Services.
The Reporting Limit (RL) is referenced as laboratory's Practical Quantitation Limit (PQL).
For Potable water analysis, the Reporting Limit (RL) is referenced as Detection Limit for reporting purposes (DLRs) defined by EPA.

If sample collected by Weck Laboratories, sampled in accordance to lab SOP MIS002

NELAC # 04229CA

The results in this report apply to the samples analyzed in accordance with the chain of custody document. Weck Laboratories certifies that the test results meet all requirements of NELAC unless noted in the Case Narrative. This analytical report must be reproduced in its entirety.

Flags for Data Qualifiers:

ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL).
Sub	Subcontracted analysis, original report enclosed.
Dil	Dilution Factor
MDL	Method Detection Limit
MDA	Minimum Detectable Activity

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

CASE NARRATIVE

Laboratory number:	**211757**
Client:	**Locus Technologies**
Project:	**27011-07-4200**
Location:	**Recycled Water Study**
Request Date:	**04/28/09**
Samples Received:	**04/28/09**

This data package contains sample and QC results for seven water samples, requested for the above referenced project on 04/28/09. The samples were received cold and intact.

Volatile Organics by GC/MS (EPA 8260B):
No analytical problems were encountered.

Metals (EPA 6010B):
High recoveries were observed for magnesium in the MS/MSD for batch 150455; the parent sample was not a project sample, and the associated RPD was within limits. No other analytical problems were encountered.

Ion Chromatography (EPA 300.0):
No analytical problems were encountered.

Total Cyanide (SM4500CN-E):
No analytical problems were encountered.

Alkalinity (SM2320B):
No analytical problems were encountered.

Total Dissolved Solids (TDS) (SM2540C):
No analytical problems were encountered.

Total Phosphorous (SM4500P-E):
No analytical problems were encountered.

Total Organic Carbon (TOC) (SM5310C):
No analytical problems were encountered.

Dissolved Organic Carbon (DOC) (SM5310C):
No analytical problems were encountered.

Surfactants (MBAS) (SM5540C):
No analytical problems were encountered.

EPA 552 (EPA 552):
Weck Laboratories, Inc. in Hacienda Heights, CA performed the analysis. Please see the Weck Laboratories, Inc. case narrative.

Type of ice used: ☒ Wet ☐ Blue/Gel ☐ None Temp(°C) 2.5 4/28/09 1800 M
ONLY 1 COOLER W/TEMP BLANK

☐ Samples Received on ice & cold without a temperature blank

☐ Samples received on ice directly from the field. Cooling process had begun

8. Were Method 5035 sampling containers present? YES [✓ NO]
If YES, what time were they transferred to freezer?

9. Did all bottles arrive unbroken/unopened? [✓ YES] NO

10. Are samples in the appropriate containers for indicated tests? YES [✓ NO]

11. Are sample labels present, in good condition and complete? [✓ YES] NO

12. Do the sample labels agree with custody papers? [✓ YES] NO

13. Was sufficient amount of sample sent for tests requested? [✓ YES] NO

14. Are the samples appropriately preserved? [✓ YES] NO N/A

15. Are bubbles > 6mm absent in VOA samples? [✓ YES] NO N/A

16. Was the client contacted concerning this sample delivery? YES NO
If YES, Who was called? By Date:

COMMENTS
SAMPLE# 5 & 6 HAA6 CONTAINER REC'D IN 250ML POLY, LIMITED SAMPLES

Certificate of Analysis

Notes:
The Chain of Custody document is part of the analytical report.
Any remaining sample(s) for testing will be disposed of one month from the final report date unless other arrangements are made in advance.
All results are expressed on wet weight basis unless otherwise specified.

An Absence of Total Coliform meets the drinking water standards as established by the State of California Department of Health Services.
The Reporting Limit (RL) is referenced as laboratory's Practical Quantitation Limit (PQL).
For Potable water analysis, the Reporting Limit (RL) is referenced as Detection Limit for reporting purposes (DLRs) defined by EPA.

If sample collected by Weck Laboratories, sampled in accordance to lab SOP MIS002

Authorized Signature

Contact: Kim G Tu (Project Manager)

ELAP # 1132
LACSD # 10143
NELAC # 04229CA

The results in this report apply to the samples analyzed in accordance with the chain of custody document. Weck Laboratories certifies that the test results meet all requirements of NELAC unless noted in the Case Narrative. This analytical report must be reproduced in its entirety.

Flags for Data Qualifiers:

ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL).
Sub	Subcontracted analysis, original report enclosed.
Dil	Dilution Factor
DL	Method Detection Limit
RL	Method Reporting Limit
MDA	Minimum Detectable Activity

EML ID: 536418

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 05-01-2009

This coversheet is included with your report in order to comply with AIHA and ISO accreditation requirements.

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Report for:

Mr. Norman Wong
Locus Technologies
299 Fairchild Dr
Mt View, CA 94043

Regarding: Project: 27011-07-4200; Recycled Water Study
EML ID: 536418

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 05-01-2009
MPN-Standard Bacteria: 05-04-2009

Project SOPs: MPN-Standard Bacteria (100130)

This coversheet is included with your report in order to comply with AIHA and ISO accreditation requirements.

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.

**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.

Group Comments

PFOS internal standard recoveries were below internal limits but within method acceptance ranges. Isotope dilution was also employed to compensate for matrix effect. Therefore, data is acceptable for reporting.

NDBA (EPA 521) MRL Check recovery was high. However, NDBA is not required for reporting. NDMA data is acceptable based on passing NDMA LCS and other QC.

The Comments Report may be blank if there are no comments for this report.

QC Ref# 510239 - Nitrosamines by GCMS by EPA 521 — Analysis Date: 05/07/2009

QC Type	Analyte	Native	Spiked	Recovered	Units	Yield (%)	Limits (%)	RPDLimit (%)	RPD%
LCS1	N-Nitroso dimethylamine (NDMA)		40	34.5	ng/l	86	(70-130)		

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

Laboratory Analyst(s)

James N. Scott
Laboratory Manager

Bromide	0.27	mg/L		

Legend:

DLR = Detection Limit For Reporting
ND = Not Detected At Or Above The DLR
NT = Not Tested
NR = Not Reported

ABS = Centimeters $^{-1}$
Cells/ml = Cells Per Milliliter
CFU/100 ml = Colony Forming Units Per 100 Milliliters
CFU/ml = Colony Forming Units Per Milliliter
cysts/L = Cysts Per Liter
Deg. C = Degrees Centigrade
mg/L = Milligrams Per Liter
MPN/100ml = Most Probable Number Per 100 Milliliters
ng/L = Nanograms Per Liter

NTU = Nephelometric Turbidity Units
oocysts/L = Oocysts Per Liter
P/A 100ml = Presence/Absence Per 100 Milliliters
pCi/L = Picocuries Per Liter
Rhod-Eqiv = Rhodamine Equivalents
T.O.N. = Threshold Odor Number
ug C/L = Micrograms Carbon Per Liter
ug/L = Micrograms Per Liter
umhos= Microhms

Data Qualifier Definitions:

A = Results may be biased high.
B = Results may be biased low.
D = Analyte is present in method blank.

E = Analyte confirmation on secondary column.
G = Sample hold time exceeded.
H = Presence verified but not quantified.
I = Sample unpreserved or improperly preserved.

J = Estimated result; value may not be accurate.
K = Too numerous to count; value represents filtration volume.
L = Matrix interference(s).
M = Field blanks not prepared at customer's request.

Batch: 56390

Report Notes:

QCS, spike recovery, and RPD values that are outside of established limits are underlined.

If an LFM recovery exceeds the established limits for any analyte, and the laboratory performance for other QC parameters is shown to be in control for that analyte, then failure is not system related but due to matrix interferences and is labeled as suspect.

Reported values that are flagged "H" are above the established acceptance range; reported values that are flagged "L" are below the acceptance range. RPD results flagge "H" are above the established RPD limit.-

Quality control sample (LFB, LFM, LFM D, QCS, QCS R, and Surrogate) reporting frequency is based on the method requirement (e.g., a QCS may not be run with every batch).

Legend:

LFB = Laboratory Fortified Blank: An aliquot of a Laboratroty Reagent Blank (LRB) to which known quantities of the method analytes are added in the laboratory. The LFB is analyzed exactly like a sample.

LFB D = Laboratory Fortified Blank Duplicate: A duplicate aliquot of an LRB to which known quantities of the method analytes are added in the laboratory. The LFB D is analyzed exactly like a sample.

LFM = Laboratory Fortified Matrix: An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyze exactly like a sample.

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory The LFM D is analyzed exactly like a sample.

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained fron a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified concentration range.

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS R is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified recovery range.

RPD = Relative Percent Difference

SUR = Surrogate. An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis.

CASE NARRATIVE

Laboratory number: **213438**
Client: **Locus Technologies**
Project: **27011-07-4200**
Location: **Recycled Water Study**
Request Date: **07/13/09**
Samples Received: **07/13/09**

This data package contains sample and QC results for nine water samples, requested for the above referenced project on 07/13/09. The samples were received cold and intact.

Volatile Organics by GC/MS (EPA 8260B):
High surrogate recoveries were observed for 1,2-dichloroethane-d4 in the method blank/BS/BSD for batch 152957. No other analytical problems were encountered.

Metals (EPA 6010B):
Low recoveries were observed for magnesium in the MS/MSD of MW-1 (lab # 213438-001); the BS/BSD were within limits, and the associated RPD was within limits. No other analytical problems were encountered.

Ion Chromatography (EPA 300.0):
No analytical problems were encountered.

Total Cyanide (SM4500CN-E):
No analytical problems were encountered.

Alkalinity (SM2320B):
No analytical problems were encountered.

Total Dissolved Solids (TDS) (SM2540C):
No analytical problems were encountered.

Total Phosphorous (SM4500P-E):
No analytical problems were encountered.

Total Organic Carbon (TOC) (SM5310C):
No analytical problems were encountered.

Dissolved Organic Carbon (DOC) (SM5310C):
High recoveries were observed for dissolved organic carbon in the MS/MSD of MW-1 (lab # 213438-001); the LCS was within limits, and the associated RPD was within limits. No other analytical problems were encountered.

Surfactants (MBAS) (SM5540C):
No analytical problems were encountered.

CASE NARRATIVE

COOLER RECEIPT CHECKLIST

Curtis & Tompkins, Ltd.

Login # 213438 Date Received 7/13/09 Number of coolers 3
Client LOCUS Project RECYCLED WATER STUDY

Date Opened 7/13/09 By (print) M VILLANUEVA (sign)
Date Logged in ✓ By (print) ✓ (sign) ✓

1. Did cooler come with a shipping slip (airbill, etc) YES [✓ NO]
Shipping info

2A. Were custody seals present? ... ☒ YES (circle) [✓ on cooler] on samples ☐ NO
How many 3 Name TOM MURPHY Date 7/13/09
2B. Were custody seals intact upon arrival? [✓ YES] NO N/A
3. Were custody papers dry and intact when received? [✓ YES] NO
4. Were custody papers filled out properly (ink, signed, etc)? [✓ YES] NO
5. Is the project identifiable from custody papers? (If so fill out top of form) [✓ YES] NO
6. Indicate the packing in cooler: (if other, describe)

☒ Bubble Wrap ☐ Foam blocks ☒ Bags ☐ None
☐ Cloth material ☐ Cardboard ☐ Styrofoam ☐ Paper towels

7. Temperature documentation:

Type of ice used: ☒ Wet ☐ Blue/Gel ☐ None Temp(°C) 3.3 7/13/09 1630 MV

☐ Samples Received on ice & cold without a temperature blank

☐ Samples received on ice directly from the field. Cooling process had begun

8. Were Method 5035 sampling containers present? YES [✓ NO]
If YES, what time were they transferred to freezer?
9. Did all bottles arrive unbroken/unopened? [✓ YES] NO
10. Are samples in the appropriate containers for indicated tests? [✓ YES] NO
11. Are sample labels present, in good condition and complete? [✓ YES] NO
12. Do the sample labels agree with custody papers? [✓ YES] NO
13. Was sufficient amount of sample sent for tests requested? [✓ YES] NO
14. Are the samples appropriately preserved? [✓ YES] NO N/A
15. Are bubbles > 6mm absent in VOA samples? YES [✓ NO] N/A
16. Was the client contacted concerning this sample delivery? YES NO
If YES, Who was called? By Date:

Certificate of Analysis

Notes:
The Chain of Custody document is part of the analytical report.
Any remaining sample(s) for testing will be disposed of one month from the final report date unless other arrangements are made in advance.
All results are expressed on wet weight basis unless otherwise specified.

An Absence of Total Coliform meets the drinking water standards as established by the State of California Department of Health Services.
The Reporting Limit (RL) is referenced as laboratory's Practical Quantitation Limit (PQL).
For Potable water analysis, the Reporting Limit (RL) is referenced as Detection Limit for reporting purposes (DLRs) defined by EPA.

If sample collected by Weck Laboratories, sampled in accordance to lab SOP MIS002

Contact: Kim G Tu (Project Manager)

ELAP # 1132
LACSD # 10143
NELAC # 04229CA

The results in this report apply to the samples analyzed in accordance with the chain of custody document. Weck Laboratories certifies that the test results meet all requirements of NELAC unless noted in the Case Narrative. This analytical report must be reproduced in its entirety.

Flags for Data Qualifiers:

ND	NOT DETECTED at or above the Reporting Limit. If J-value reported, then NOT DETECTED at or above the Method Detection Limit (MDL).
Sub	Subcontracted analysis, original report enclosed.
Dil	Dilution Factor
DL	Method Detection Limit
RL	Method Reporting Limit
MDA	Minimum Detectable Activity

Regarding: Project: 27011-07-4200; Recycled Water Study
EML ID: 559919

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 07-16-2009

This coversheet is included with your report in order to comply with AIHA and ISO accreditation requirements.

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.

**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.

Group Comments

NDMA MS Duplicate recovery was low on the initial run (518363). However, QC recoveries for subsequent runs were within method requirements. Therefore, data is acceptable for reporting.

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

Laboratory Analyst(s)

Legend:

DLR = Detection Limit For Reporting
ND = Not Detected At Or Above The DLR
NT = Not Tested
NR = Not Reported

ABS = Centimeters $^{-1}$
Cells/ml = Cells Per Milliliter
CFU/100 ml = Colony Forming Units Per 100 Milliliters
CFU/ml = Colony Forming Units Per Milliliter
cysts/L = Cysts Per Liter
Deg. C = Degrees Centigrade
mg/L = Milligrams Per Liter
MPN/100ml = Most Probable Number Per 100 Milliliters
ng/L = Nanograms Per Liter

NTU = Nephelometric Turbidity Units
oocysts/L = Oocysts Per Liter
P/A 100ml = Presence/Absence Per 100 Milliliters
pCi/L = Picocuries Per Liter
Rhod-Eqiv = Rhodamine Equivalents
T.O.N. = Threshold Odor Number
ug C/L = Micrograms Carbon Per Liter
ug/L = Micrograms Per Liter
umhos= Microhms

Data Qualifier Definitions:

A = Results may be biased high.
B = Results may be biased low.
D = Analyte is present in method blank.

E = Analyte confirmation on secondary column.
G = Sample hold time exceeded.
H = Presence verified but not quantified.
I = Sample unpreserved or improperly preserved.

J = Estimated result; value may not be accurate.
K = Too numerous to count; value represents filtration volume.
L = Matrix interference(s).
M = Field blanks not prepared at customer's request.

LFM D	Phosphate	Spike Amount: 1	1.75	mg/L		%Rec: 93	90 - 110	0.6		15
LFM D	Phosphate	Spike Amount: 1	1.86	mg/L		%Rec: 90	90 - 110	0.5		15
QCS R	Phosphate	1	1.00	mg/L		%Rec: 100	90 - 110			

Report Notes:

QCS, spike recovery, and RPD values that are outside of established limits are underlined.

If an LFM recovery exceeds the established limits for any analyte, and the laboratory performance for other QC parameters is shown to be in control for that analyte, then failure is not system related but due to matrix interferences and is labeled as suspect.

Reported values that are flagged "H" are above the established acceptance range; reported values that are flagged "L" are below the acceptance range. RPD results flagge "H" are above the established RPD limit.-

Quality control sample (LFB, LFM, LFM D, QCS, QCS R, and Surrogate) reporting frequency is based on the method requirement (e.g., a QCS may not be run with every batch).

Legend:

LFB = Laboratory Fortified Blank: An aliquot of a Laboratroty Reagent Blank (LRB) to which known quantities of the method analytes are added in the laboratory. The LFB i analyzed exactly like a sample.

LFB D = Laboratory Fortified Blank Duplicate: A duplicate aliquot of an LRB to which known quantities of the method analytes are added in the laboratory. The LFB D is analyzed exactly like a sample.

LFM = Laboratory Fortified Matrix: An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyze exactly like a sample.

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory The LFM D is analyzed exactly like a sample.

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained fron a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified concentration range.

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS R i obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified recovery range.

RPD = Relative Percent Difference

SUR = Surrogate. An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis.

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

CASE NARRATIVE

Laboratory number:	**215257**
Client:	**Locus Technologies**
Project:	**27011-07-4200**
Location:	**Recycled Water Study**
Request Date:	**09/28/09**
Samples Received:	**09/28/09**

This data package contains sample and QC results for seven water samples, requested for the above referenced project on 09/28/09. The samples were received cold and intact.

Volatile Organics by GC/MS (EPA 8260B):
No analytical problems were encountered.

Metals (EPA 6010B):
High recovery was observed for calcium in the MS for batch 155519; the parent sample was not a project sample, the BS/BSD were within limits, and the associated RPD was within limits. No other analytical problems were encountered.

Ion Chromatography (EPA 300.0):
No analytical problems were encountered.

Total Cyanide (SM4500CN-E):
No analytical problems were encountered.

Alkalinity (SM2320B):
No analytical problems were encountered.

Total Dissolved Solids (TDS) (SM2540C):
No analytical problems were encountered.

Total Phosphorous (SM4500P-E):
High recoveries were observed for phosphorous in the MS/MSD for batch 155735; the parent sample was not a project sample, the LCS was within limits, and the associated RPD was within limits. No other analytical problems were encountered.

Total Organic Carbon (TOC) (SM5310C):
No analytical problems were encountered.

Dissolved Organic Carbon (DOC) (SM5310C):
Low recoveries were observed for dissolved organic carbon in the MS/MSD for batch 155716; the parent sample was not a project sample, the LCS was within limits, and the associated RPD was within limits. The results for sample L5-comp (Lab # 215257-006) had an RSD greater than 10%. No sample remains to re-analyze. Data was qualified with a b. No other analytical problems were encountered.

CASE NARRATIVE

Laboratory number: **215257**
Client: **Locus Technologies**
Project: **27011-07-4200**
Location: **Recycled Water Study**
Request Date: **09/28/09**
Samples Received: **09/28/09**

Surfactants (MBAS) (SM5540C):
No analytical problems were encountered.

EPA 552 (EPA 552):
Columbia Analytical Services in Kelso, WA performed the analysis. Please see the Columbia Analytical Services case narrative.

COOLER RECEIPT CHECKLIST

Curtis & Tompkins, Ltd.

Login # 215257 Date Received 9/28/09 Number of coolers 3

Client LOCUS Project RECYCLED WATER STUDY

Date Opened 9/28/09 By (print) M VILLANUEVE (sign)

Date Logged in ✓ By (print) ✓ (sign) ✓

1. Did cooler come with a shipping slip (airbill, etc) YES [✓ NO]

   Shipping info

2A. Were custody seals present? ... ☒ YES (circle) [✓ on cooler] on samples ☐ NO

   How many 3 Name TONY MURPHY Date 9/28/09

2B. Were custody seals intact upon arrival? [✓ YES] NO N/A

3. Were custody papers dry and intact when received? [✓ YES] NO

4. Were custody papers filled out properly (ink, signed, etc)? [✓ YES] NO

5. Is the project identifiable from custody papers? (If so fill out top of form) [✓ YES] NO

6. Indicate the packing in cooler: (if other, describe)

   ☒ Bubble Wrap ☐ Foam blocks ☐ Bags ☐ None

   ☐ Cloth material ☐ Cardboard ☐ Styrofoam ☐ Paper towels

7. Temperature documentation:

   Type of ice used: ☒ Wet ☐ Blue/Gel ☐ None Temp(°C) 2.6 9/28/09 1000 MV

   ☐ Samples Received on ice & cold without a temperature blank ONLY 1 COOLER W/ TEMP BLANK

   ☐ Samples received on ice directly from the field. Cooling process had begun

8. Were Method 5035 sampling containers present? YES [✓ NO]

   If YES, what time were they transferred to freezer?

9. Did all bottles arrive unbroken/unopened? [✓ YES] NO

10. Are samples in the appropriate containers for indicated tests? [✓ YES] NO

11. Are sample labels present, in good condition and complete? [✓ YES] NO

12. Do the sample labels agree with custody papers? [✓ YES] NO

13. Was sufficient amount of sample sent for tests requested? [✓ YES] NO

14. Are the samples appropriately preserved? [✓ YES] NO N/A

15. Are bubbles > 6mm absent in VOA samples? [✓ YES] NO N/A

16. Was the client contacted concerning this sample delivery? YES NO

    If YES, Who was called? By Date:

RE: Recycled Water Study/215257

Dear Micah:

Enclosed are the results of the samples submitted to our laboratory on October 02, 2009. For your reference, these analyses have been assigned our service request number K0909404.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program. The test results meet requirements of the current NELAP standards, where applicable, and except as noted in the laboratory case narrative provided. For a specific list of NELAP-accredited analytes, refer to the certifications section at www.caslab.com. All results are intended to be considered in their entirety, and Columbia Analytical Services, Inc. (CAS) is not responsible for use of less than the complete report. Results apply only to the items submitted to the laboratory for analysis and individual items (samples) analyzed, as listed in the report.

Please call if you have any questions. My extension is 3281. You may also contact me via Email at PDivvela@caslab.com.

Respectfully submitted,

Columbia Analytical Services, Inc.

Pradeep Divvela
Project Chemist

Acronyms

ASTM	American Society for Testing and Materials
A2LA	American Association for Laboratory Accreditation
CARB	California Air Resources Board
CAS Number	Chemical Abstract Service registry Number
CFC	Chlorofluorocarbon
CFU	Colony-Forming Unit
DEC	Department of Environmental Conservation
DEQ	Department of Environmental Quality
DHS	Department of Health Services
DOE	Department of Ecology
DOH	Department of Health
EPA	U. S. Environmental Protection Agency
ELAP	Environmental Laboratory Accreditation Program
GC	Gas Chromatography
GC/MS	Gas Chromatography/Mass Spectrometry
LUFT	Leaking Underground Fuel Tank
M	Modified
MCL	Maximum Contaminant Level is the highest permissible concentration of a substance allowed in drinking water as established by the USEPA.
MDL	Method Detection Limit
MPN	Most Probable Number
MRL	Method Reporting Limit
NA	Not Applicable
NC	Not Calculated
NCASI	National Council of the Paper Industry for Air and Stream Improvement
ND	Not Detected
NIOSH	National Institute for Occupational Safety and Health
PQL	Practical Quantitation Limit
RCRA	Resource Conservation and Recovery Act
SIM	Selected Ion Monitoring
TPH	Total Petroleum Hydrocarbons
tr	Trace level is the concentration of an analyte that is less than the PQL but greater than or equal to the MDL.

Inorganic Data Qualifiers

*	The result is an outlier. See case narrative.
#	The control limit criteria is not applicable. See case narrative.
B	The analyte was found in the associated method blank at a level that is significant relative to the sample result.
E	The result is an estimate amount because the value exceeded the instrument calibration range.
J	The result is an estimated concentration that is less than the MRL or LOQ but greater than or equal to the MDL or LOD.
U	The compound was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.1 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The LOD has been adjusted for dilution.
i	The MRL/MDL or LOQ/LOD has been elevated due to a matrix interference.
X	See case narrative.
Q	See case narrative. One or more quality control criteria was outside the limits.

Metals Data Qualifiers

#	The control limit criteria is not applicable. See case narrative.
J	The result is an estimated concentration that is less than the MRL or LOQ but greater than or equal to the MDL or LOD.
E	The percent difference for the serial dilution was greater than 10%, indicating a possible matrix interference in the sample.
M	The duplicate injection precision was not met.
N	The Matrix Spike sample recovery is not within control limits. See case narrative.
S	The reported value was determined by the Method of Standard Additions (MSA).
U	The compound was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.1 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The LOD has been adjusted for any dilution or
W	The post-digestion spike for furnace AA analysis is out of control limits, while sample absorbance is less than 50% of spike absorbance.
i	The MRL/MDL or LOQ/LOD has been elevated due to a matrix interference.
X	See case narrative.
+	The correlation coefficient for the MSA is less than 0.995.
Q	See case narrative. One or more quality control criteria was outside the limits.

Organic Data Qualifiers

*	The result is an outlier. See case narrative.
#	The control limit criteria is not applicable. See case narrative.
A	A tentatively identified compound, a suspected aldol-condensation product.
B	The analyte was found in the associated method blank at a level that is significant relative to the sample result.
C	The analyte was qualitatively confirmed using GC/MS techniques, pattern recognition, or by comparing to historical data.
D	The reported result is from a dilution.
E	The result is an estimate amount because the value exceeded the instrument calibration range.
J	The result is an estimated concentration that is less than the MRL but greater than or equal to the MDL.
N	The result is presumptive. The analyte was tentatively identified, but a confirmation analysis was not performed.
P	The GC or HPLC confirmation criteria was exceeded. The relative percent difference is greater than 40% between the two analytical results.
U	The compound was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.1 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The LOD has been adjusted for any dilution or
i	The MRL/MDL or LOQ/LOD has been elevated due to a chromatographic interference.
X	See case narrative.
Q	See case narrative. One or more quality control criteria was outside the limits.

Additional Petroleum Hydrocarbon Specific Qualifiers

F	The chromatographic fingerprint of the sample matches the elution pattern of the calibration standard.
L	The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of lighter molecular weight constituents than the calibration standard.
H	The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of heavier molecular weight constituents than the calibration standard.
O	The chromatographic fingerprint of the sample resembles an oil, but does not match the calibration standard.
Y	The chromatographic fingerprint of the sample resembles a petroleum product eluting in approximately the correct carbon range, but the elution pattern does not match the calibration standard.
Z	The chromatographic fingerprint does not resemble a petroleum product.

COLUMBIA ANALYTICAL SERVICES, INC.

Client:	Curtis & Tompkins, Ltd.	**Service Request No.:**	K0909404
Project:	Recycled Water Study	**Date Received:**	10/02/09
Sample Matrix:	Water		

CASE NARRATIVE

All analyses were performed consistent with the quality assurance program of Columbia Analytical Services, Inc. (CAS). This report contains analytical results for samples designated for Tier II data deliverables. When appropriate to the method, method blank results have been reported with each analytical test. Surrogate recoveries have been reported for all applicable organic analyses. Additional quality control analyses reported herein include: Matrix Spike (MS), and Laboratory Control Sample (LCS).

Sample Receipt

Seven water samples were received for analysis at Columbia Analytical Services on 10/02/09. The samples were received in good condition and consistent with the accompanying chain of custody form. The samples were stored in a refrigerator at 4°C upon receipt at the laboratory.

Haloacetic Acids by EPA Method 552.2

No anomalies associated with the analysis of these samples were observed.

Cooler Receipt and Preservation Form

Client / Project: Curtis & Tompkins Service Request *K09* 09404

Received: 10/2/09 Opened: 10/2/09 By: 77

1. Samples were received via? *US Mail* *Fed Ex* *UPS* *DHL* *GH* *GS* *PDX* [✓ *Courier* California Overnight] *Hand Delivered*
2. Samples were received in: (circle) [✓ *Cooler*] *Box* *Envelope* *Other*______ *NA*
3. Were custody seals on coolers? NA Y [✓ N] If yes, how many and where? NA

   If present, were custody seals intact? ~~Y N~~ NA If present, were they signed and dated? ~~Y N~~ NA
4. Is shipper's air-bill filed? If not, record air-bill number:______ [✓ NA] Y N
5. **Temperature of cooler(s) upon receipt (°C):** -0.8

   Temperature Blank (°C):

   Thermometer ID: 259
6. If applicable, list Chain of Custody Numbers:
7. Packing material used. *Inserts* [✓ *Baggies*] [✓ *Bubble Wrap*] *Gel Packs* [✓ *Wet Ice*] *Sleeves* *Other*______
8. Were custody papers properly filled out (ink, signed, etc.)? NA [✓ Y] N
9. **Did all bottles arrive in good condition (unbroken)?** *Indicate in the table below.* NA [✓ Y] N
10. Were all sample labels complete (i.e analysis, preservation, etc.)? NA [✓ Y] N
11. Did all sample labels and tags agree with custody papers? *Indicate in the table below* NA [✓ Y] N
12. **Were appropriate bottles/containers and volumes received for the tests indicated?** NA [✓ Y] N
13. Were the pH-preserved bottles tested* received at the appropriate pH? *Indicate in the table below* [✓ NA] Y N
14. Were VOA vials received without headspace? *Indicate in the table below.* [✓ NA] Y N
15. **Are CWA Microbiology samples received with >1/2 the 24hr. hold time remaining from collection?** [✓ NA] Y N
16. Was C12/Res negative? [✓ NA] Y N

Sample ID on Bottle	Sample ID on COC	Sample ID on Bottle	Sample ID on COC

Sample ID	Bottle Count Bottle Type	Out of Temp	Head-space	Broke	pH	Reagent	Volume added	Reagent Lot Number	Initials	Time

**Does not include all pH preserved sample aliquots received. See sample receiving SOP (SMO-GEN).*

Regarding: Project: 27011-07-4200; Recycled Water Study
EML ID: 585425

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 10-01-2009
MPN-Standard Bacteria: 10-02-2009

Project SOPs: MPN-Standard Bacteria (100130)

This coversheet is included with your report in order to comply with AIHA and ISO accreditation requirements.

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.

**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

QC Ref# 526997 - NTA and EDTA by Ion Chromatography by MWH_MET **Analysis Date: 10/02/2009**

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

Legend:

DLR = Detection Limit For Reporting
ND = Not Detected At Or Above The DLR
NT = Not Tested
NR = Not Reported

ABS = Centimeters $^{-1}$
Cells/ml = Cells Per Milliliter
CFU/100 ml = Colony Forming Units Per 100 Milliliters
CFU/ml = Colony Forming Units Per Milliliter
cysts/L = Cysts Per Liter
Deg. C = Degrees Centigrade
mg/L = Milligrams Per Liter
MPN/100ml = Most Probable Number Per 100 Milliliters
ng/L = Nanograms Per Liter

NTU = Nephelometric Turbidity Units
oocysts/L = Oocysts Per Liter
P/A 100ml = Presence/Absence Per 100 Milliliters
pCi/L = Picocuries Per Liter
Rhod-Eqiv = Rhodamine Equivalents
T.O.N. = Threshold Odor Number
ug C/L = Micrograms Carbon Per Liter
ug/L = Micrograms Per Liter
umhos= Microhms

Report Notes:

QCS, spike recovery, and RPD values that are outside of established limits are underlined.

If an LFM recovery exceeds the established limits for any analyte, and the laboratory performance for other QC parameters is shown to be in control for that analyte, then failure is not system related but due to matrix interferences and is labeled as suspect.

Reported values that are flagged "H" are above the established acceptance range; reported values that are flagged "L" are below the acceptance range. RPD results flagged "H" are above the established RPD limit.-

Quality control sample (LFB, LFM, LFM D, QCS, QCS R, and Surrogate) reporting frequency is based on the method requirement (e.g., a QCS may not be run with every batch).

Legend:

LFB = Laboratory Fortified Blank: An aliquot of a Laboratroty Reagent Blank (LRB) to which known quantities of the method analytes are added in the laboratory. The LFB is analyzed exactly like a sample.

LFB D = Laboratory Fortified Blank Duplicate: A duplicate aliquot of an LRB to which known quantities of the method analytes are added in the laboratory. The LFB D is analyzed exactly like a sample.

LFM = Laboratory Fortified Matrix: An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyze exactly like a sample.

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM D is analyzed exactly like a sample.

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified concentration range.

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS R is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified recovery range.

RPD = Relative Percent Difference

SUR = Surrogate. An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis.

Mt View, CA 94043

Regarding: Project: 27011-07-4200; Recycled Water Study
EML ID: 592608

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
Heterotrophic plate count: 10-22-2009
MPN-Standard Bacteria: 10-26-2009

Project SOPs: MPN-Standard Bacteria (100130)

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

E. coli	SM 9221 F	10/19/09 13:00	< 2	-	14

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.

**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

LFM D	Phosphate	Spike Amount: 1	1.67	mg/L		%Rec: 90.8	90 - 110	0.2		15
QCS R	Phosphate	3	3.05	mg/L		%Rec: 101.5	90 - 110			

Report Notes:

QCS, spike recovery, and RPD values that are outside of established limits are underlined.

If an LFM recovery exceeds the established limits for any analyte, and the laboratory performance for other QC parameters is shown to be in control for that analyte, then failure is not system related but due to matrix interferences and is labeled as suspect.

Reported values that are flagged "H" are above the established acceptance range; reported values that are flagged "L" are below the acceptance range. RPD results flagged "H" are above the established RPD limit.-

Quality control sample (LFB, LFM, LFM D, QCS, QCS R, and Surrogate) reporting frequency is based on the method requirement (e.g., a QCS may not be run with every batch).

Legend:

LFB = Laboratory Fortified Blank: An aliquot of a Laboratroty Reagent Blank (LRB) to which known quantities of the method analytes are added in the laboratory. The LFB is analyzed exactly like a sample.

LFB D = Laboratory Fortified Blank Duplicate: A duplicate aliquot of an LRB to which known quantities of the method analytes are added in the laboratory. The LFB D is analyzed exactly like a sample.

LFM = Laboratory Fortified Matrix: An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyzed exactly like a sample.

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM D is analyzed exactly like a sample.

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified concentration range.

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS F is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified recovery range.

RPD = Relative Percent Difference

SUR = Surrogate. An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis.

CASE NARRATIVE

Laboratory number:	**217244**
Client:	**Locus Technologies**
Project:	**27011-07-4200**
Location:	**Recycled Water Study**
Request Date:	**12/14/09**
Samples Received:	**12/14/09**

This data package contains sample and QC results for seven water samples, requested for the above referenced project on 12/14/09. The samples were received cold and intact.

Volatile Organics by GC/MS (EPA 8260B):
No analytical problems were encountered.

Metals (EPA 6010B):
No analytical problems were encountered.

Ion Chromatography (EPA 300.0):
No analytical problems were encountered.

Total Cyanide (SM4500CN-E):
No analytical problems were encountered.

Alkalinity (SM2320B):
No analytical problems were encountered.

Total Dissolved Solids (TDS) (SM2540C):
No analytical problems were encountered.

Total Phosphorous (SM4500P-E):
High recovery was observed for phosphorous in the MS for batch 158420; the parent sample was not a project sample, and the LCS was within limits. High RPD was also observed for phosphorous in the MS/MSD for batch 158420. No other analytical problems were encountered.

Total Organic Carbon (TOC) (SM5310C):
No analytical problems were encountered.

Dissolved Organic Carbon (DOC) (SM5310C):
No analytical problems were encountered.

Surfactants (MBAS) (SM5540C):
High recovery was observed for surfactants (MBAS) in the MS of SOURCE (lab # 217244-007); the LCS was within limits, the associated RPD was within limits, and this analyte was not detected at or above the RL in the associated sample. No other analytical problems were encountered.

COOLER RECEIPT CHECKLIST

Curtis & Tompkins, Ltd.

Login # 217244 Date Received 12/14/09 Number of coolers 3

Client LOCUS Project RECYCLED WATER STUDY

Date Opened 12/14/09 By (print) M. VILLANUEVA (sign)

Date Logged in ✓ By (print) ✓ (sign) ✓

1. Did cooler come with a shipping slip (airbill, etc) YES [✓ NO]

   Shipping info

2A. Were custody seals present? ... ☒ YES (circle) [✓ on cooler] on samples ☐ NO

   How many 3 Name T. MURPHY Date 12/14/09

2B. Were custody seals intact upon arrival? [✓ YES] NO N/A

3. Were custody papers dry and intact when received? [✓ YES] NO

4. Were custody papers filled out properly (ink, signed, etc)? [✓ YES] NO

5. Is the project identifiable from custody papers? (If so fill out top of form) [✓ YES] NO

6. Indicate the packing in cooler: (if other, describe)

   ☒ Bubble Wrap
   ☐ Cloth material
   ☐ Foam blocks
   ☐ Cardboard
   ☒ Bags
   ☐ Styrofoam
   ☐ None
   ☐ Paper towels

7. Temperature documentation:

   Type of ice used: ☒ Wet ☐ Blue/Gel ☐ None Temp(°C) 1.5

   ONLY 1 COOLER w/TEMP BLANK 12/14/09 2050 MV

   ☐ Samples Received on ice & cold without a temperature blank

   ☐ Samples received on ice directly from the field. Cooling process had begun

8. Were Method 5035 sampling containers present? YES [✓ NO]

   If YES, what time were they transferred to freezer?

9. Did all bottles arrive unbroken/unopened? [✓ YES] NO

10. Are samples in the appropriate containers for indicated tests? [✓ YES] NO

11. Are sample labels present, in good condition and complete? [✓ YES] NO

12. Do the sample labels agree with custody papers? [✓ YES] NO

13. Was sufficient amount of sample sent for tests requested? [✓ YES] NO

14. Are the samples appropriately preserved? [✓ YES] NO N/A

15. Are bubbles > 6mm absent in VOA samples? [✓ YES] NO N/A

16. Was the client contacted concerning this sample delivery? YES NO

   If YES, Who was called? By Date:

RE: Recycled Water Study/217244

Dear Micah:

Enclosed are the revised pages for the samples submitted to our laboratory on December 17, 2009. For your reference, these analyses have been assigned our service request number K0912243.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program. The test results meet requirements of the current NELAP standards, where applicable, and except as noted in the laboratory case narrative provided. For a specific list of NELAP-accredited analytes, refer to the certifications section at www.caslab.com. All results are intended to be considered in their entirety, and Columbia Analytical Services, Inc. (CAS) is not responsible for use of less than the complete report. Results apply only to the items submitted to the laboratory for analysis and individual items (samples) analyzed, as listed in the report.

Please call if you have any questions. My extension is 3281. You may also contact me via Email at PDivvela@caslab.com.

Respectfully submitted,

Columbia Analytical Services, Inc.

Pradeep Divvela
Project Chemist

PD/cb

Results flagged with an asterisk (*) indicate values outside control criteria.

Results flagged with a pound (#) indicate the control criteria is not applicable.

Percent recoveries and relative percent differences (RPD) are determined by the software using values in the calculation which have not been rounded.

Report for:

Mr. Norman Wong
Locus Technologies
299 Fairchild Dr
Mt View, CA 94043

Regarding: Project: 27011-07-4200
EML ID: 609788

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
MPN-Standard Bacteria: 12-21-2009

Service SOPs: MPN-Standard Bacteria (100130)

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.
**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.
‡ A "Version" indicated by -"x" after the Lab ID# with a value greater than 1 indicates a sample with amended data. The revision number is reflected by the value of "x".

Laboratory Comments
Report: #321459

Locus Technologies
Norman Wong
299 Fairchild Drive
Mountain View, CA 94043

Flags Legend:

S7 - Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.

The Comments Report may be blank if there are no comments for this report.

MBLK	N-Nitrosopyrollidine (NPYR)			<2	ng/L				

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

Phone: (408) 265-2607 ext. 3228 - Fax: (408) 979-5680

Batch: 59160

QC Code	Test Name		Reported Value	Units	Flag		Acceptance Range	RPD	Flag	RPD Limit
LFB	Bromide	Spike Amount: 1	1.08	mg/L		%Rec: 108.2	90 - 110			
LFM	Bromide	Spike Amount: 1	1.34	mg/L		%Rec: 101.8	90 - 110			
LFM D	Bromide	Spike Amount: 1	1.34	mg/L		%Rec: 101.9	90 - 110	0.1		15
QCS R	Bromide	1	1.10	mg/L		%Rec: 110	90 - 110			
LFB	Phosphate	Spike Amount: 2	2.00	mg/L		%Rec: 100	90 - 110			
LFM	Phosphate	Spike Amount: 1	2.16	mg/L		%Rec: 97.1	90 - 110			
LFM D	Phosphate	Spike Amount: 1	2.17	mg/L		%Rec: 97.8	90 - 110	0.3		15
QCS R	Phosphate	3	3.11	mg/L		%Rec: 103.7	90 - 110			

Report Notes:

QCS, spike recovery, and RPD values that are outside of established limits are underlined.

If an LFM recovery exceeds the established limits for any analyte, and the laboratory performance for other QC parameters is shown to be in control for that analyte, then failure is not system related but due to matrix interferences and is labeled as suspect.

Reported values that are flagged "H" are above the established acceptance range; reported values that are flagged "L" are below the acceptance range. RPD results flagged "H" are above the established RPD limit.-

Quality control sample (LFB, LFM, LFM D, QCS, QCS R, and Surrogate) reporting frequency is based on the method requirement (e.g., a QCS may not be run with every batch).

Legend:

LFB = Laboratory Fortified Blank: An aliquot of a Laboratroty Reagent Blank (LRB) to which known quantities of the method analytes are added in the laboratory. The LFB is analyzed exactly like a sample.

LFB D = Laboratory Fortified Blank Duplicate: A duplicate aliquot of an LRB to which known quantities of the method analytes are added in the laboratory. The LFB D is analyzed exactly like a sample.

LFM = Laboratory Fortified Matrix: An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyzed exactly like a sample.

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM D is analyzed exactly like a sample.

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified concentration range.

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS R is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified recovery range.

RPD = Relative Percent Difference

SUR = Surrogate. An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis.

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

San Jose, CA 95118

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

CASE NARRATIVE

Laboratory number:	**218531**
Client:	**Locus Technologies**
Project:	**27011-07-4200**
Location:	**Recycled Water Study**
Request Date:	**03/01/10**
Samples Received:	**03/01/10**

This data package contains sample and QC results for nine water samples, requested for the above referenced project on 03/01/10. The samples were received cold and intact.

Volatile Organics by GC/MS (EPA 8260B):
No analytical problems were encountered.

Metals (EPA 6010B):
No analytical problems were encountered.

Ion Chromatography (EPA 300.0):
No analytical problems were encountered.

Total Cyanide (SM4500CN-E):
No analytical problems were encountered.

Alkalinity (SM2320B):
No analytical problems were encountered.

Total Dissolved Solids (TDS) (SM2540C):
No analytical problems were encountered.

Total Phosphorous (SM4500P-E):
No analytical problems were encountered.

Total Organic Carbon (TOC) (SM5310C):
No analytical problems were encountered.

Dissolved Organic Carbon (DOC) (SM5310C):
No analytical problems were encountered.

Surfactants (MBAS) (SM5540C):
No analytical problems were encountered.

EPA 552 (EPA 552):
Columbia Analytical Services in Kelso, WA performed the analysis (NELAP certified). Please see the Columbia Analytical Services case narrative.

COOLER RECEIPT CHECKLIST

Curtis & Tompkins, Ltd.

Login # 218531 Date Received 3/1/10 Number of coolers 5
Client LOCUS Project RECYCLED WATER STUDY

Date Opened 3/1/10 By (print) M. VILLANUEVA (sign)
Date Logged in ↓ By (print) ↓ (sign) ↓

1. Did cooler come with a shipping slip (airbill, etc) YES [✓ NO]
Shipping info

2A. Were custody seals present? ... ☒ YES (circle) [✓ on cooler] on samples ☐ NO
How many 5 Name T. MURPHY Date 3/1/10

2B. Were custody seals intact upon arrival? [✓ YES] NO N/A

3. Were custody papers dry and intact when received? [✓ YES] NO

4. Were custody papers filled out properly (ink, signed, etc)? [✓ YES] NO

5. Is the project identifiable from custody papers? (If so fill out top of form) [✓ YES] NO

6. Indicate the packing in cooler: (if other, describe)

☒ Bubble Wrap ☐ Foam blocks ☒ Bags ☐ None
☐ Cloth material ☐ Cardboard ☐ Styrofoam ☐ Paper towels

7. Temperature documentation:

Type of ice used: ☒ Wet ☐ Blue/Gel ☐ None Temp(°C) 1.0 3/1/10 1707 MV
ONLY 1 COOLER W/ TEMP BLANK

☐ Samples Received on ice & cold without a temperature blank

☐ Samples received on ice directly from the field. Cooling process had begun

8. Were Method 5035 sampling containers present? YES [✓ NO]
If YES, what time were they transferred to freezer?

9. Did all bottles arrive unbroken/unopened? [✓ YES] NO

10. Are samples in the appropriate containers for indicated tests? [✓ YES] NO

11. Are sample labels present, in good condition and complete? [✓ YES] NO

12. Do the sample labels agree with custody papers? [✓ YES] NO

13. Was sufficient amount of sample sent for tests requested? YES [✓ NO]

14. Are the samples appropriately preserved? [✓ YES] NO N/A

15. Are bubbles > 6mm absent in VOA samples? [✓ YES] NO N/A

16. Was the client contacted concerning this sample delivery? YES NO
If YES, Who was called? By Date:

RE: Recycled Water Study/218531

Dear Micah:

Enclosed are the results of the samples submitted to our laboratory on March 04, 2010. For your reference, these analyses have been assigned our service request number K1001987.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program. The test results meet requirements of the current NELAP standards, where applicable, and except as noted in the laboratory case narrative provided. For a specific list of NELAP-accredited analytes, refer to the certifications section at www.caslab.com. All results are intended to be considered in their entirety, and Columbia Analytical Services, Inc. (CAS) is not responsible for use of less than the complete report. Results apply only to the items submitted to the laboratory for analysis and individual items (samples) analyzed, as listed in the report.

Please call if you have any questions. My extension is 3281. You may also contact me via Email at PDivvela@caslab.com.

Respectfully submitted,

Columbia Analytical Services, Inc.

Pradeep Divvela
Project Chemist

Acronyms

ASTM	American Society for Testing and Materials
A2LA	American Association for Laboratory Accreditation
CARB	California Air Resources Board
CAS Number	Chemical Abstract Service registry Number
CFC	Chlorofluorocarbon
CFU	Colony-Forming Unit
DEC	Department of Environmental Conservation
DEQ	Department of Environmental Quality
DHS	Department of Health Services
DOE	Department of Ecology
DOH	Department of Health
EPA	U. S. Environmental Protection Agency
ELAP	Environmental Laboratory Accreditation Program
GC	Gas Chromatography
GC/MS	Gas Chromatography/Mass Spectrometry
LUFT	Leaking Underground Fuel Tank
M	Modified
MCL	Maximum Contaminant Level is the highest permissible concentration of a substance allowed in drinking water as established by the USEPA.
MDL	Method Detection Limit
MPN	Most Probable Number
MRL	Method Reporting Limit
NA	Not Applicable
NC	Not Calculated
NCASI	National Council of the Paper Industry for Air and Stream Improvement
ND	Not Detected
NIOSH	National Institute for Occupational Safety and Health
PQL	Practical Quantitation Limit
RCRA	Resource Conservation and Recovery Act
SIM	Selected Ion Monitoring
TPH	Total Petroleum Hydrocarbons
tr	Trace level is the concentration of an analyte that is less than the PQL but greater than or equal to the MDL.

Inorganic Data Qualifiers

*	The result is an outlier. See case narrative.
#	The control limit criteria is not applicable. See case narrative.
B	The analyte was found in the associated method blank at a level that is significant relative to the sample result as defined by the DOD or NELAC standards.
E	The result is an estimate amount because the value exceeded the instrument calibration range.
J	The result is an estimated value that was detected outside the quantitation range.
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.1 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
i	The MRL/MDL or LOQ/LOD is elevated due to a matrix interference.
X	See case narrative.
Q	See case narrative. One or more quality control criteria was outside the limits.

Metals Data Qualifiers

#	The control limit criteria is not applicable. See case narrative.
J	The result is an estimated value that was detected outside the quantitation range.
E	The percent difference for the serial dilution was greater than 10%, indicating a possible matrix interference in the sample.
M	The duplicate injection precision was not met.
N	The Matrix Spike sample recovery is not within control limits. See case narrative.
S	The reported value was determined by the Method of Standard Additions (MSA).
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.1 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
W	The post-digestion spike for furnace AA analysis is out of control limits, while sample absorbance is less than 50% of spike absorbance.
i	The MRL/MDL or LOQ/LOD is elevated due to a matrix interference.
X	See case narrative.
+	The correlation coefficient for the MSA is less than 0.995.
Q	See case narrative. One or more quality control criteria was outside the limits.

Organic Data Qualifiers

*	The result is an outlier. See case narrative.
#	The control limit criteria is not applicable. See case narrative.
A	A tentatively identified compound, a suspected aldol-condensation product.
B	The analyte was found in the associated method blank at a level that is significant relative to the sample result as defined by the DOD or NELAC standards.
C	The analyte was qualitatively confirmed using GC/MS techniques, pattern recognition, or by comparing to historical data.
D	The reported result is from a dilution.
E	The result is an estimate amount because the value exceeded the instrument calibration range.
J	The result is an estimated value that was detected outside the quantitation range.
N	The result is presumptive. The analyte was tentatively identified, but a confirmation analysis was not performed.
P	The GC or HPLC confirmation criteria was exceeded. The relative percent difference is greater than 40% between the two analytical results.
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.1 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
i	The MRL/MDL or LOQ/LOD is elevated due to a chromatographic interference.
X	See case narrative.
Q	See case narrative. One or more quality control criteria was outside the limits.

Additional Petroleum Hydrocarbon Specific Qualifiers

F	The chromatographic fingerprint of the sample matches the elution pattern of the calibration standard.
L	The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of lighter molecular weight constituents than the calibration standard.
H	The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of heavier molecular weight constituents than the calibration standard.
O	The chromatographic fingerprint of the sample resembles an oil, but does not match the calibration standard.
Y	The chromatographic fingerprint of the sample resembles a petroleum product eluting in approximately the correct carbon range, but the elution pattern does not match the calibration standard.
Z	The chromatographic fingerprint does not resemble a petroleum product.

COLUMBIA ANALYTICAL SERVICES, INC.

Client:	Curtis & Tompkins, Ltd.	**Service Request No.:**	K1001987
Project:	Recycled Water Study	**Date Received:**	03/04/10
Sample Matrix:	Drinking Water		

CASE NARRATIVE

All analyses were performed consistent with the quality assurance program of Columbia Analytical Services, Inc. (CAS). This report contains analytical results for samples designated for Tier II data deliverables. When appropriate to the method, method blank results have been reported with each analytical test. Surrogate recoveries have been reported for all applicable organic analyses. Additional quality control analyses reported herein include: Matrix Spike (MS), and Laboratory Control Sample (LCS).

Sample Receipt

Nine water samples were received for analysis at Columbia Analytical Services on 03/04/10. The samples were received in good condition and consistent with the accompanying chain of custody form. The samples were stored in a refrigerator at 4°C upon receipt at the laboratory.

Haloacetic Acids by EPA 552.2

Sample Notes and Discussion:
The control criteria for matrix spike recovery of Trichloroacetic Acid for Batch QC were not applicable. The analyte concentration in the sample was significantly higher than the added spike concentration, preventing accurate evaluation of the spike recovery.

No other anomalies associated with the analysis of these samples were observed.

Regarding: Project: 27011-07-4200; Recycled Water Study
EML ID: 631523

Approved by:

Lab Manager
Dr. Kamashwaran Ramanathan

Dates of Analysis:
MPN-Standard Bacteria: 03-08-2010

Service SOPs: MPN-Standard Bacteria (100130)

For clarity, we report the number of significant digits as calculated; but, due to the nature of this type of biological data, the number of significant digits that is used for interpretation should generally be one or two. All samples were received in acceptable condition unless noted in the Report Comments portion in the body of the report. Due to the nature of the analyses performed, field blank corrections of results is not a standard practice. The results relate only to the items tested.

EMLab P&K ("the Company") shall have no liability to the client or the client's customer with respect to decisions or recommendations made, actions taken or courses of conduct implemented by either the client or the client's customer as a result of or based upon the Test Results. In no event shall the Company be liable to the client with respect to the Test Results except for the Company's own willful misconduct or gross negligence nor shall the Company be liable for incidental or consequential damages or lost profits or revenues to the fullest extent such liability may be disclaimed by law, even if the Company has been advised of the possibility of such damages, lost profits or lost revenues. In no event shall the Company's liability with respect to the Test Results exceed the amount paid to the Company by the client therefor.

Comments:

*MPN - Most Probable Number.
MPN methods:
SM - Standard Methods for the Examination of Waters and Wastewaters, 20th ed. 1998.
FDA BAM - U.S. Food and Drug Administration Bacteriological Analytical Manual, January 2001.
MPN values are calculated using the method of Thomas (1942).
The MPN method was developed to handle samples with a high load of particulate matter, such as turbid waters, soils, wastewaters and sludges. MPN values are statistically derived calculations of viable bacterial density based on the assumptions of random distribution of single, non-clustered, bacteria not attached to particulate matter within a sample. Due to the fact that bacteria can cluster and adhere to materials, values determined by the MPN method should be considered estimates in many instances.
**The Upper 95% Confidence Limit (UCL) and Lower 95% Confidence Limit (LCL) are calculated using the method of deMan (1983) and represent that "before the tubes are inoculated, the chance is at least 95 percent that the confidence interval associated with the eventual result will enclose the actual concentration" (FDA BAM).
Interpretation is left to the company and/or persons who conducted the field work.
‡ A "Version" indicated by -"x" after the Lab ID# with a value greater than 1 indicates a sample with amended data. The revision number is reflected by the value of "x".

MWH LABS USE ONLY:

LOGIN COMMENTS: ____

SAMPLES CHECKED AGAINST COC BY: RSR

SAMPLES LOGGED IN BY: RSR

SAMPLE TEMP WHEN REC'D AT LAB: 4°C (Compliance: 6°C or Below)

CONDITION OF BLUE ICE: FROZEN X PARTIALLY FROZEN ___ THAWED ___ (check for yes)

SAMPLES REC'D DAY OF COLLECTION? ☐ (check for yes) (check for yes)

TO BE COMPLETED BY SAMPLER:

COMPANY, UTILITY or PROJECT: Locus Technologies

SYSTEM #:

COMPLIANCE SAMPLES ☐ - Requires state forms ☐

NON-COMPLIANCE SAMPLES ☐

REGULATION INVOLVED: (eg. SDWA, Phase V, NPDES, FDA,...)

Type of samples (circle one): ROUTINE SPECIAL CONFIRMATION

MWH LABS CLIENT CODE: locus

P.O.# / JOB # / PROJECT : 27011-07-7000

SEE ATTACHED BOTTLE ORDER FOR ANALYSES ☐ (check for yes), OR

LIST ANALYSES REQUIRED BELOW (enter number of bottles sent for each test for each sample):

SAMPLER PRINTED NAME AND SIGNATURE: H. Castro / T. Murphy

TAT requested: rush by adv notice only

STD X 1 week ___ 3 day ___ 2 day ___ 1 day ___

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

QC Ref# 545145 - Perfluorinated compounds by MWH PFC **Analysis Date: 03/04/2010**

Spike recovery is already corrected for native results.
Spikes which exceed Limits and Method Blanks with positive results are highlighted by Underlining.
Criteria for MS and Dup are advisory only, batch control is based on LCS. Criteria for duplicates are advisory only, unless otherwise specified in the method.
(S) Indicates surrogate compound.
(I) Indicates internal standard compound.
RPD not calculated for LCS2 when different a concentration than LCS1 is used
RPD not calculated for Duplicates when the result is not five times the MRL (Minimum Reporting Level)

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

Certificate of Analysis - QC Report

Santa Clara Valley Water District Laboratory
1026 Blossom Hill Road - San Jose, CA 95123
Phone: (408) 265-2607 ext. 3228 - Fax: (408) 979-5680

Batch: 60007

QC Code	Test Name		Reported Value	Units	Flag		Acceptance Range	RPD	Flag	RPD Limit
LFB	Bromide	Spike Amount: 1	0.99	mg/L		%Rec: 99	90 - 110			
LFM	Bromide	Spike Amount: 1	1.25	mg/L		%Rec: 96.9	90 - 110			
LFM D	Bromide	Spike Amount: 1	1.25	mg/L		%Rec: 97	90 - 110	0.1		15
QCS R	Bromide	1	0.99	mg/L		%Rec: 99.1	90 - 110			

Report Notes:

QCS, spike recovery, and RPD values that are outside of established limits are underlined.

If an LFM recovery exceeds the established limits for any analyte, and the laboratory performance for other QC parameters is shown to be in control for that analyte, then failure is not system related but due to matrix interferences and is labeled as suspect.

Reported values that are flagged "H" are above the established acceptance range; reported values that are flagged "L" are below the acceptance range. RPD results flagged "H" are above the established RPD limit.-

Quality control sample (LFB, LFM, LFM D, QCS, QCS R, and Surrogate) reporting frequency is based on the method requirement (e.g., a QCS may not be run with every batch).

Legend:

LFB = Laboratory Fortified Blank: An aliquot of a Laboratroty Reagent Blank (LRB) to which known quantities of the method analytes are added in the laboratory. The LFB is analyzed exactly like a sample.

LFB D = Laboratory Fortified Blank Duplicate: A duplicate aliquot of an LRB to which known quantities of the method analytes are added in the laboratory. The LFB D is analyzed exactly like a sample.

LFM = Laboratory Fortified Matrix: An aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM is analyzed exactly like a sample.

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM D is analyzed exactly like a sample.

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified concentration range.

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS F is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified recovery range.

RPD = Relative Percent Difference

SUR = Surrogate. An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis.

Dear Henry Barrientos,

This transmits the analytical results for the Laboratory services that you requested. The data contained herein are supported by the Laboratory Services Unit's Quality Assurance/Quality Control Program.

The analytical results, quality control information, and sample handling observations have been reviewed for both completeness and accuracy, with any exceptions noted.

LFM D = Laboratory Fortified Matrix Duplicate: A duplicate aliquot of an environmental sample to which known quantities of the method analytes are added in the laboratory. The LFM D is analyzed exactly like a sample.

QCS = Quality Control Sample: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified concentration range.

QCS R = Quality Control Sample Recovery: A solution of method analytes of known concentrations which is used to fortify an aliquot of LRB or sample matrix. The QCS R is obtained from a source external to the laboratory and different from the source of calibration standards. Result is weighed against a specified recovery range.

RPD = Relative Percent Difference

SUR = Surrogate. An organic compound that is similar in chemical composition to the analytes of interest and spiked into environmental and batch QC samples prior to sample preparation and analysis.

Notes

* Detections of VOCs include TCE, cis-1,2-DCE and Freon 11

See Table III-4-2 for Legend of Qualifiers.

TABLE III-4-2
LEGEND OF QUALIFIERS
PILOT STUDY
RECYCLED WATER STUDY

Flag	Description
B	Low recovery in MS/MSD and RPD out of limits.
BB	Target analyte detected in method blank at or above the laboratory minimum reporting limit (MRL). No major impact on the reported result since the target analyte is 10x the concentration level.
BD	Target analyte detected in method blank is above CA DHS recommended value of 0.5 and did not meet the internal blank limit of 1/3 MRL (1/3 of MRL = 0.7).
D	Field duplicate sample was out of RPD limits from regular sample.
J	The result is an estimated value detected outside the quantitation range.
L3	The associated blank spike reocvery was above method acceptance limits.
NA	Not analyzed.
ND	Not detected.
P	GC or HPLC confirmation criteria was exceeded. The RPD is greater than 40% between the two analytical results.
R4	MS/MSD RPD out exceeded method limits.
S7	Surrogate recovery was below laboratory and method acceptance limits. Unable to confirm matrix effect.
T	Detection found in associated trip blank.

EXECUTIVE SUMMARY

Volume IV of this report assesses the soil aquifer treatment (SAT) capacity and groundwater degradation potential from expanded use of recycled water in the Santa Clara and Llagas Groundwater Subbasins. The goal of Volume IV is to geographically rate the SAT capacity and groundwater degradation potential throughout the study area. The evaluation relies on findings from the bench test and pilot study to calibrate the evaluation specific to the study area. To assess a rating in a geographical manner, the study utilizes AutoCAD Map 3D software to analyze multiple layers of geographic information system (GIS) data.

Soil Aquifer Treatment Capacity

SAT capacity is defined as the ability of the soil and aquifer to naturally treat contaminants. For this study, the focus is contaminants found in recycled water. The approach to delineating SAT capacity in the study area utilizes the hydrogeological characteristics of the given area including the depth to groundwater ("D"), the type of shallow soil media ("S") and the type of vadose zone media ("I"). The methodology for determining SAT capacity is an adaptation of EPA's DRASTIC system created for evaluating the relative groundwater pollution potential using hydrogeologic settings (USEPA, 1987). SAT capacity is determined by a weighted average of the rating of each input ("D", "S", and "I").

Depth to groundwater ("D") is the physical distance the water travels from the surface to reach the groundwater in the target aquifer. The target aquifer of concern is the principal aquifer which is the confined aquifer where a confining layer exists and the shallowest aquifer for unconfined areas. The rating for the depth to groundwater is calibrated on depth-specific results from the pilot study. The majority of the depth to water in the Santa Clara Subbasin in the confined areas was over 100 feet bgs. In the unconfined areas for the Santa Clara Subbasin, depth to groundwater ranged between 0 and 100 feet. Very few areas were below five feet bgs. In the Llagas Subbasin, the majority of the depth to groundwater in the confined area was more than 100 ft bgs. In the unconfined portions of the Llagas Subbasin, depth to groundwater ranged from 0 to 100 feet bgs. The weighting of the depth groundwater relative to the other input parameters is 49%. The weighting is calibrated from the soil attenuation model which examined the relative importance between each input.

Soil media (“S”) refers to the first several feet of soil below the ground surface. This is taken to be approximately six feet or less. The soil in this depth range is generally characterized by a high amount of organic matter. Major attenuative processes that occur in the soil media include biodegradation, filtration, volatilization, and sorption. Rating for the soil media is calibrated on results from the bench test which examined constituent removal from a range of soil cores with different grain size distributions. The majority of the Santa Clara Subbasin has a soil media classified as sandy loam or clay loam. The soil media in the northern section of the Santa Clara Subbasin is dominated by clay. For the Llagas Subbasin the major soil media is sandy loam followed by clay loam and silty loam. The weighting of the soil media relative to the other input parameters is 25%. The weighting is calibrated from the soil attenuation model which examined the relative importance between each input.

Impact of vadose zone media (“I”) refers to the depth above the water table in the unsaturated or partially saturated zone. The vadose zone is significant because it provides attenuation through biodegradation, filtration, volatilization, dispersion, and chemical reaction. Within the study area, the vadose zone media can be variable over depth. For unconfined areas, the representative vadose zone media for each area is determined by using the net hydraulic conductivity for the vadose zone soil profile. For areas with confined aquifers, the layer that controls the attenuation processes is the confining layer. Therefore, a value for the confining layer is assigned to confined areas. Rating for the vadose zone media is calibrated on results from the bench test which examined constituent removal from a range of soil cores with different grain size distributions. The vadose zone media in the Santa Clara and Llagas Subbasins in the confined area is the confining layer. The dominant vadose zone media in the Santa Clara Subbasin in the unconfined area is the clay. For the Llagas Subbasin, the dominant vadose zone media in the unconfined area is clay followed by silt. The weighting of the soil media relative to the other input parameters is 26%. The weighting is calibrated from the soil attenuation model which examined the relative importance between each input.

Soil Aquifer Treatment (SAT) capacity maps are found in Figure IV-2-11 and IV-2-12 for the Santa Clara and Llagas Subbasin respectively. Based on a relative scale, the SAT rating ranges from 1 to 10 (high to least capacity). The confined areas of both subbasins were determined to have relatively high SAT capacity due to the confining layer and deep depth to groundwater. The unconfined areas were largely of good or average capacity. Only a few areas in the unconfined area were regarded as having relatively marginal capacity and even fewer areas were regarded as least capacity. Areas with a lower rating tended to be characterized with shallow depth to water and a coarse grain size distribution in the vadose zone.

Groundwater Degradation Potential

Groundwater degradation potential is defined as the potential for groundwater to be impacted by recycled water used in irrigation. Groundwater is regarded as impacted when the quality is worse than current groundwater quality, with the consideration of the available assimilative capacity. For the purpose of this study, the available assimilative capacity is determined by comparing current groundwater quality with applicable water quality standards, and calculating 20% of the difference between those two values. For constituents where the current groundwater concentration exceeds the water quality standard, there is zero available assimilative capacity for that constituent.

The approach to delineating groundwater degradation potential in the study area is dependent on (1) the hydrogeological characteristics (SAT capacity) and (2) the quality of the recycled water applied for a given area. Compared to the additive approach in evaluating SAT capacity, the input parameters for the groundwater degradation potential are more appropriately evaluated in a multiplicative method. The maximum score for groundwater degradation potential is 100.

SAT capacity rating can range from 1 to 10, such that 10 is indicative of poor SAT capacity and 1 is indicative of high SAT capacity. The recycled water quality rating also ranges from 1 to 10, such that 10 is indicative of relatively poor recycled water quality (generally higher constituent concentrations), and 1 is indicative of relatively high recycled water quality (generally lower constituent concentrations).

The recycled water quality rating is dependent on (1) the concentration of the recycled water applied, (2) the threat of each constituent determined in Volume III of this study, and (3) representative groundwater quality in the study area. The recycled water quality is evaluated based on an aggregate index method using multiple subindices. In this case, the subindices refer to the constituents. The aggregate index is normalized to a scale from 1 to 10. A rating of 10 is indicative of relatively low recycled water quality (maximum recycled water concentrations) and a rating of 1 is indicative of relatively high recycled water quality (recycled water concentrations equal to groundwater concentrations).

Groundwater degradation potential maps are found in IV-3-3 and IV-3-4 for the Santa Clara and Llagas Subbasin respectively. Groundwater degradation potential in the Santa Clara Subbasin is largely of lowest to average potential with a few areas regarded as high or highest. The rating in the Santa Clara Subbasin ranges from 8 to 96. Groundwater degradation potential in the Llagas Subbasin is largely of lowest to average potential and with a few areas regarded as high. The evaluation did not find any areas of the highest potential in the Llagas Subbasin. In the Llagas Subbasin, the groundwater degradation potential rating ranges from 11 to 70. Comparatively, the Santa Clara and Llagas Subbasins share a similar distribution in groundwater degradation potential with a majority of lowest and low potential found in the confined areas and more average potential in the unconfined areas.

VOLUME IV
EVALUATION OF POTENTIAL IMPACTS
RECYCLED WATER STUDY

1. INTRODUCTION

This report was prepared by Locus Technologies (Locus) on behalf of the Santa Clara Valley Water District (SCVWD) for the Recycled Water Irrigation and Groundwater Study (Study). Volume IV assesses the soil aquifer treatment capacity and potential to degrade groundwater quality across the project study area.

This document provides a qualitative screening approach that employs the best professional judgment to extrapolate data from the findings of the previous phases of this study to the entire study area. Previous phases of this study are the literature review and data analysis (Volume I), the soil attenuation model and bench test (Volume II), and the pilot study (Volume III). These earlier phases compiled and reported information that was used to prepare the analysis discussed in Volume IV.

1.1. Purpose

This volume reports the findings from the evaluation of soil aquifer treatment capacity and groundwater degradation potential in the Santa Clara and Llagas Subbasins. The results of the evaluation serve as a tool for determining what quality of recycled water is needed to prevent groundwater quality impacts in specific geographic areas. The findings from this evaluation are important towards determining recycled water screening levels, best management practices, and monitoring recommendation discussed in Volume V. The following goals were identified for the evaluation:

- Provide a comparative evaluation for soil aquifer treatment capacity, specific to recycled water as an irrigation source, for any given location in the project study area.
- Provide a comparative evaluation for the groundwater degradation potential for any given location using the local recycled water sources in the project study area.

The focus of this phase of the study is chemical constituents, including those of anthropogenic and non-anthropogenic origins that have been evaluated in the previous phases of the study (Volumes I to III). A few constituents of concern are biological.

Soil aquifer treatment capacity is defined as the ability of the soil and aquifer to naturally treat contaminants. The study's focus is on contaminants found in recycled water. Mechanisms to lower the concentrations of contaminants include but are not exclusive to volatilization, dispersion, diffusion, sorption, precipitation, ion exchange, oxidation-reduction, transformation, and filtration. Soil aquifer treatment capacity is established from the hydrogeological characteristics of a given area.

Groundwater degradation potential is defined as the potential for groundwater to be impacted by recycled water used in irrigation. Groundwater is regarded as impacted when the quality is worse than current groundwater quality, with the consideration of the available assimilative capacity. Groundwater degradation potential is not only determined by the hydrogeological characteristics of a given area but is also dependent on the quality of the recycled water applied.

1.2. Approach

To determine regional zones for soil aquifer treatment capacity and groundwater degradation potential, AutoCAD Map 3D software was used to compile and evaluate the criteria discussed. AutoCAD Map 3D is a mapping software tool for visualizing, managing, creating and analyzing geographic information system (GIS) data. Multiple sets of geographic data are used to determine relative soil aquifer treatment capacity and groundwater degradation potential.

The methodology used in this document is an adaptation of EPA's DRASTIC system, adapted to the use of recycled water for irrigation using the findings from the pilot study, bench test, soil attenuation model, and literature review. DRASTIC was published in 1987 and lays out an established methodology for evaluating groundwater pollution potential using hydrogeologic settings (USEPA, 1987).

The core of DRASTIC's evaluation system is a weighting and rating system of several factors. The methodology used in this document is an adaptation of the DRASTIC evaluation system using a rating from one to ten and a weighted average of each of the factors. The criteria incorporate a range of hydrogeological factors from the surface and subsurface. Hydrogeological factors at the surface include the topography area and the amount of recharge entering the system. In the subsurface, hydrogeological factors include the depth to groundwater, the type of soils in the subsurface, and the hydraulic conductivity of the aquifer. The adapted evaluation utilizes a subset of these factors which were found to be relevant to the evaluation of recycled water irrigation's potential effect on groundwater. Each criterion is weighted, by a percentage, which depend on the level of relevance. The sum of all the weighting from each criterion is equal to 100%. The numerical evaluation allows for a comparison of different areas of the relative risk of degradation from the use of recycled water use in irrigation.

The values for each criterion are ranked (up to 10), reflecting the criterion's impact on soil treatment capacity or groundwater degradation potential. A higher rating denotes lower soil treatment capacity and consequently greater groundwater degradation potential. For example, areas with a greater depth to groundwater would have greater soil attenuation capacity and would be assigned a low rating. Areas with a shallow depth to groundwater (i.e. high water table) would have less soil attenuation capacity and would be therefore given the highest rating for this input.

2. SOIL AQUIFER TREATMENT CAPACITY

Soil aquifer treatment capacity is the ability of the soil and aquifer to naturally remove contaminants. The unsaturated or vadose zone acts as a natural filter and can lower the concentration of constituents found in recycled water. Additional reduction is achieved in the aquifer from residence time in the aquifer before extraction for beneficial use. Mechanisms to lower the concentrations of contaminants of concern include volatilization, dispersion, diffusion, sorption, precipitation, ion exchange, oxidation-reduction, transformation, and filtration. For the purpose of this study, general physical parameters of the soil are used to help evaluate the combined potential for soil aquifer treatment rather than attempting to quantify each mechanism separately. Findings from the previous phases of the study, namely the literature review, data analysis, soil modeling, bench test and pilot test, were used to support a comparative evaluation of soil aquifer treatment capacity.

For this study, the soil aquifer treatment capacity focuses on attenuation that is achieved before reaching groundwater. Attenuation that is potentially achieved in the aquifer is not considered part of the soil aquifer treatment capacity for this study. Assimilative capacity differs from soil aquifer treatment capacity, in that assimilative capacity refers to the capacity of the groundwater to degrade without affecting beneficial use. Soil aquifer treatment capacity in this study refers to the capacity of the subsurface to remove contaminants before reaching groundwater.

2.1. Methodology

2.1.1. DRASTIC

DRASTIC was published in 1987 by the EPA. DRASTIC lays out a methodology for evaluating groundwater pollution potential using hydrogeologic settings (USEPA, 1987). DRASTIC is a system of weighted ratings. The name, DRASTIC, is an acronym for the seven major factors in the rating system that includes depth to water (“D”), net recharge (“R”), aquifer media (“A”), soil media (“S”), topography (“T”), impact of the vadose zone media (“I”), and hydraulic conductivity of the aquifer (“C”) (USEPA, 1987). Using the DRASTIC method as a starting point, the values and relative importance of these inputs were adapted using data collected from previous phases of this study, as discussed below for each input.

2.1.2. Evaluation Assumptions

Assumptions in this evaluation are

1) The contaminant is introduced at the ground surface through application of recycled water. The study is concerned with recycled water as an irrigation source, which is applied at the surface. Typically, irrigation is applied at the surface; however recycled water can also be introduced using buried drip irrigation systems with buried emitters. Buried irrigation systems are still located close to the surface, where the root zone is located. Therefore, the assumption of surface application is still appropriate.

2) The contaminant is flushed and moved advectively toward groundwater by precipitation and irrigation. If attenuative processes were not present, the fate of a contaminant would be towards the groundwater. The assumption also implies that there is no runoff. By regulation, no volume of recycled water is allowed as runoff, and irrigation systems should be maintained and adjusted so that no runoff occurs.

3) For areas with both a confined and unconfined aquifer, the groundwater of concern for the purpose of this evaluation is in the confined aquifer. In portions of the study area, an unconfined aquifer lies atop a confined aquifer. The groundwater that is used in these areas is typically from the confined aquifer which is considered to be the principal groundwater supply aquifer. Therefore, the input parameters for the confined areas relate to the deep, confined zone rather than the shallow unconfined zone. This evaluation may not be protective for shallow unconfined groundwater where a confined deeper aquifer is also present.

4) Percolation is not short circuited by fractures. The evaluation assumes that preferential flow paths from fractures or other vertical conduits (e.g. abandoned wells) are not present. Percolation occurs through the pores of the soil matrix.

2.1.3. GIS Tool

To determine regional zones for soil aquifer treatment capacity and groundwater degradation potential, AutoCAD Map 3D software was used to compile and evaluate the factors discussed. AutoCAD Map 3D is a mapping software tool for visualizing, managing, creating and analyzing geographic information system (GIS) data. Multiple sets of geographic data are factored into determining soil aquifer treatment capacity.

2.2. Evaluation Criteria

2.2.1. Depth to Water

The depth to groundwater is the vertical distance water must travel from the surface to reach groundwater. In general, a longer distance allows for more contact time through the soil for attenuation processes to occur. As discussed in Section 2.1.1, the target aquifer of concern is the confined aquifer where the principal groundwater supply aquifer is protected by a confining layer, and the shallowest aquifer for all unconfined areas. Values for this input are based on this assumption, so that the depth to the top of the aquifer is used for confined areas, and the depth to the water table is used for unconfined areas.

In the Santa Clara Subbasin, depth to shallow groundwater ranges from 0 to over 100 feet bgs (SCVWD, 2004). The principal aquifer depth in confined areas of the Santa Clara Subbasin was over 100 feet bgs. In the Llagas Subbasin, the depth to shallow groundwater varies from 10 to 100 feet bgs in the northeast region of the basin to less than five feet bgs to the south. The principal aquifer depth in confined areas of the Llagas Subbasin ranges from 50 ft bgs to over 100 ft bgs.

2.2.1.1. Derivation of Ratings

Ratings for the Depth to Water input were derived and calibrated using results from the pilot study in Volume III, as shown in Table IV-2-1. The pilot study included sampling of recycled water constituents in the irrigation source water and also in the subsurface at five feet, at ten feet, and in the groundwater (approximately 30 feet bgs).

From the pilot study, the percentage of removal of total haloacetic acids (HAA6) was used as the indicator for the attenuation capacity at different depths. HAA6 was selected for this purpose because (1) it was consistently quantifiable in the recycled water sources and in the subsurface, (2) this constituent is the sum of six analytical constituents and therefore less prone to analytical variability, and (3) within the pilot study, the only origin of this constituent is from recycled water. The concentration of HAA6 in the recycled water source was calculated as the average total HAA6 concentration for all eight sampling events, to represent the net contribution of this constituent over the entire duration of the pilot study. The concentration of HAA6 in the subsurface was calculated as the average of the last two events of the pilot study, so that long-term conditions can be represented without relying entirely on a single sampling event.

Removal percentages of HAA6 were calculated by comparing the concentrations at 5 feet, 10 feet, and 30 feet to the concentration in the recycled water used for irrigation. The percentage removal at 10 feet and 30 feet were then compared to the percentage removal at 5 feet. This ratio represents the increased attenuation capacity at depths of 10 feet and 30 feet compared to 5 feet. From this analysis, there was 1.14 times more attenuation capacity at 10 feet, and 1.31 times more attenuation capacity at 30 feet, compared to 5 feet. The Depth to Water rating for 5 feet (DRASTIC default of 10) is then adjusted by these factors to obtain Depth to Water ratings for 10 feet and 30 feet. Values for other depths were extrapolated from the calibrated values using a trend line as shown in Figure IV-2-1 and can be expressed as

$$[\text{Depth to Water Rating}] = 12.544\times[\text{Depth to Water}]^{-0.1483}$$

A geometric trend was used to fit the data because the rate of removal is expected to be constant over depth for a given soil type.

Depth to Water		
Weighting: 49%		
Range (ft)	Default DRASTIC Rating	Customized Rating
0-5	10	10
5-15	9	8.4
15-30	7	7.6
30-50	5	7.0
50-75	3	6.6
75-100	2	6.3
100+	1	6.0

Compared to the default DRASTIC rating, the customized rating has a shorter range (6 to 10).

2.2.1.1.1.Sensitivity Analysis

A sensitivity analysis was done on the derivation using haloacetic acid data due to the limited data in the groundwater. Results of the sensitivity analysis are also included in Table IV-2-1. For the haloacetic acid data in groundwater, there was one detected value which was qualified (“J” flag). Specifically, this value is 0.26 J µg/L for the monochloroacetic acid in MW-2 in the eighth sampling event. The “J” flag indicates that the value is an estimate between the method detection limit and the laboratory reporting limit. Estimates in this range are at a lower confidence than detection at or above the reporting limit. Because of the reliance on this one data point, the sensitivity of the results using this value was tested by substituting the value for zero (Scenario 1) and for the reporting limit (2 µg/L) (Scenario 2).

The resulting ratings from the sensitivity analysis did not reveal significant changes to the DRASTIC ratings. In scenario 1, the ratings did not change from the base scenario. There was a slightly higher percentage removal at 30 feet but the change was not prominent enough to affect the depth to water rating. In scenario 2, the ratings did not change significantly from the base scenario. There was a lower percentage removal at 30 feet and this translated into a slightly higher depth to water rating at 30 feet (7.9 as opposed to 7.6). Overall, the derivation for the depth to water rating was determined to have low sensitivity to the specified groundwater data point within the range between 0 and 2 µg/L.

2.2.1.2. Data and Calculation

GIS data for the depth to water was supplied from the SCVWD website and from *Groundwater Vulnerability Study, Santa Clara County, California* (SCVWD, 2010). Geographic data for depth to water was determined by two different sources of data: one set for confined areas, and another for unconfined areas. For the unconfined areas in the Santa Clara and Llagas Subbasins, data was derived from the SCVWD using minimum depth to water measurements at fuel leak sites. Data from fuel leak sites for the coverage spanned from 1980 to just prior to the publication date (October 15, 2003) of the geographic data. For unconfined areas, the depth to water is the distance from the ground surface to the water table.

For confined areas, the depth to groundwater is the distance from the ground surface to top of the confined aquifer. Data for this is defined using the depth to the top of the first well screen of public water supply wells. Data for depth to groundwater for confined aquifers was obtained from *Groundwater Vulnerability Study, Santa Clara County, California* (SCVWD, 2010).

The depth to water ratings for Santa Clara and Llagas Groundwater Subbasins, as calculated from the depth to water data, are shown on Figures IV-2-2 and IV-2-3. Depth to water is given a weighting factor of 49%. The weighting factor is determined using a calibration method with the soil attenuation model. Section 2.4 describes in detail the procedure for establishing the weighting factor.

2.2.2. Soil Media

The soil media refers to the first several feet of soil from the land surface, commonly an average of six feet or less. The soil in this zone is generally characterized by a high amount of organic matter. Organic matter is composed of undecayed plant and animal tissue, charcoal and humic substances. Humic substances are largely responsible for adsorption and complexation processes in the soil. Soil provides attenuation of recycled water contaminants through biodegradation, filtration, volatilization, and sorption. Biodegradation and volatilization, as well as organic content, decrease with depth. Coverage of soil media was determined from a previous DRASTIC analysis of the study area conducted by the SCVWD (SCVWD, 1999). The coverage used a soil map developed by the United States Soil Conservation Service. The soil classifications were analyzed and assigned for each area.

Soil media was found to be a significant factor in how well a recycled water constituent was attenuated. In the soil attenuation model and bench test, the study verified that constituents generally attenuate better in fine grain soils, followed by semifine and coarse soils.

2.2.2.1. Derivation of Ratings

Ratings for the soil media input were calibrated using results from the bench test in Volume II, as shown in Table IV-2-2. The bench test included eight soil cores, which were irrigated with recycled water. The soil cores were selected to represent different soil types observed within the study area. The recycled water used in the bench test was obtained from the SJ/SC WPCP and the SCRWA Plant in Gilroy. Five of the eight soil cores irrigated with recycled water from the bench test yielded sufficient effluent for chemical analysis. These cores are listed in Table IV-2-2, with the soil characterization of each core as originally documented, and also as would be classified for the DRASTIC soil media input.

From the bench test, the percentage of removal of total trihalomethanes was used as the indicator for the attenuation capacity of the varying soil types. Total trihalomethanes were selected for this purpose because (1) they were consistently quantifiable in the recycled water sources and in the effluent from each of the soil cores, (2) this constituent is the sum of four analytical constituents and therefore less prone to analytical variability, and (3) within the bench test, trihalomethanes can be uniquely attributed to the recycled water source. Removal percentages of total trihalomethanes were calculated by comparing the final effluent sample from each core to the initial recycled water influent sample for each core. The final effluent sample was used to better represent long-term conditions, and the initial influent sample was used to account for the estimated travel time through the soil cores.

Because the soil cores varied in length, the percentage removals for the four-foot soil cores were normalized to one foot. This calculation was done assuming a constant percentage removal over each foot of the four-foot soil cores, using the following equation:

$$[\text{1-ft Removal}] = 1 - (1 - [\text{4-ft Removal}])^{1/4}$$

Once normalized, the percentage removal of total trihalomethanes from each soil core was compared to the percentage removal through sand. This ratio represents the increased attenuation capacity for silt and clay compared to sand. From this analysis, the silt core had 1.70 times more attenuation capacity than sand, and the clay cores had 3.63 to 3.86 times more attenuation capacity than sand. The soil media rating for sand (DRASTIC default of 7) is then adjusted by these factors to obtain soil media ratings for silt and clay. Values for soil types not included in the bench test were interpolated from the calibrated values for sand, silty loam, and massive clay.

Soil media is ranked in the following categories:

Soil Media		
Weighting: 25%		
Range	Default DRASTIC Rating	Customized Rating
Sand Loam to Sand	7	7
Sandy Loam	6	6
Silty Loam	4	4
Clay Loam	3	3
Massive Clay	1	2

2.2.2.2. *Data and Calculations*

Soil media data were obtained from *Groundwater Vulnerability Study, Santa Clara County, California* (SCVWD, 2010). Soil media in the study area include sand loam to sand, sandy loam, silty loam, clay loam, and massive clay. Soil media rating is determined accordingly with grain size which affects the hydraulic conductivity. Soils with high clay content have lower hydraulic conductivity which slows the transport of constituents and increases the time for filtration and other attenuative processes. Shrinking/aggregated clays are characterized by their significant capacity to expand and contract. Montmorillonite and smectite are examples of expansive clays.

The soil media ratings for Santa Clara and Llagas Groundwater Subbasins are shown on Figures IV-2-4 and IV-2-5. Soil media is given a weighting factor of 25%. The weighting factor is determined using a calibration method with the soil attenuation model. Section 2.4 of this volume describes in detail the procedure for establishing the weighting factor.

2.2.3. Impact of the Vadose Zone Media

The impact of the vadose media refers to the depth above the water table in the unsaturated or partially saturated zone. For confined aquifers, the vadose zone includes the aquitard and the unconfined aquifer above the top of the aquifer and below the soil. The vadose zone provides attenuation of recycled water contaminants through biodegradation, filtration, volatilization, dispersion, and chemical reaction. Biodegradation and volatilization decrease with depth.

Categories for the vadose zone media depend on whether the aquifer is confined or unconfined. Following DRASTIC procedure, the lithologic layer that most significantly controls the attenuation potential for each area is used to represent the vadose zone. For areas with a confined aquifer the appropriate vadose zone medium is the confining layer, since the presence of a confining layer controls the attenuation and transport through the vadose zone. For unconfined areas, the representative vadose zone medium is determined by calculating the net hydraulic conductivity through the entire vadose zone, and assigning the vadose zone medium that best represents that hydraulic conductivity.

2.2.3.1. Derivation of Ratings

The attenuation capacity for the vadose zone can be evaluated using the same approach used for the soil media described in Section 2.2.2. Therefore, the calibration of this input follows a similar procedure, with the ratio of total trihalomethane removal being used to derive vadose zone media ratings for silt and clay from the rating for sand (default of 6 for the sand end of the range). The derivation of these ratings is shown on Table IV-2-2, and the results are summarized below.

Impact of the Vadose Zone Media			
Weighting: 26%			
Range	DRASTIC Default Rating	DRASTIC Default Typical Rating	Customized Rating
Confining Layer	1	1	1
Clay	2-6	3	2
Silt	2-6	3	3
Loam	4-8	6	4
Sand	6-9	8	6
Gravel	6-9	8	9

2.2.3.2. Data and Calculations

GIS data for the vadose zone media was calculated using SCVWD's database of lithology data for wells, and the GIS depth to water data discussed in Section 2.2.1. First, the depth to water values were extracted from the GIS data at each well where lithology data were available. The lithology data set was then filtered to remove data below the depth to water, so that only lithology data for the unsaturated vadose zone remained. The lithology information at each location was then categorized and assigned hydraulic conductivity values using values from Fetter (1994) as shown in Table IV-2-3. For soil types that include multiple grain sizes, the category was selected based on the best representation of hydraulic conductivity, which generally corresponds to the fine-grained material.

Net vertical hydraulic conductivity at each location was then calculated using the following equation (Fetter, 1994):

$$[\text{net hydraulic conductivity}] = \frac{\sum_{m=1}^{n} [\text{layer thickness}]_m}{\sum_{m=1}^{n} \frac{[\text{layer thickness}]_m}{[\text{layer hydraulic conductivity}]_m}}$$

This equation combines the hydraulic conductivities for each lithologic layer into a single value at each location. The net hydraulic conductivities were then converted back into a soil type using the value ranges listed in Table IV-2-3. Those values were then developed into a data set for the entire study area using thiessen polygons. The net result is a distribution of soil types that adequately characterize the vadose zone over the study area. In all confined areas, the vadose zone rating was set to 1, because the confining layer controls this input for those areas.

The impact to vadose ratings for Santa Clara and Llagas Groundwater Subbasins are shown on Figures IV-2-6 and IV-2-7. Impact of vadose zone media is given a weighting factor of 26%. The weighting factor is determined using a calibration method with the soil attenuation model. Section 2.4 describes in detail the procedure for establishing the weighting factor.

2.3. Omitted Evaluation Criteria

Several input factors that are included as part of the standard DRASTIC evaluation process were not included in the adapted version for this study. Those factors and the rationale for their omission from this study are discussed below.

2.3.1. Net Recharge

Net recharge is the amount of water per unit area that percolates from the surface to the groundwater and is typically represented by precipitation. In this study, irrigation serves as an additional source of recharge. Recharge water is the main vehicle for leaching and transporting contaminants downward. The greater the net recharge, the greater the potential for transport of contaminants to groundwater.

Net recharge is not included in this evaluation. Net recharge for this study is predominantly water from irrigation rather than precipitation. In the pilot study, nearly 80% of water at the surface was from irrigation. The remaining 20% was from precipitation. Geographically, the water needs for similar types of vegetation are not expected to vary greatly across the Santa Clara and Llagas Subbasins. This is because reference evapotranspiration rates, associated with irrigation rates, are the same throughout the study area (CIMIS, 1999). In addition, the landscaping and irrigation rates may be modified at any time by property owners, making it inappropriate to set a fixed value for net recharge at any location. Annual precipitation rates in the Santa Clara and Llagas Subbasins, from 1961 to 1990, approximately range from 5 to 25 inches per year (Natural Resources Conservation Services, 1961 to 1990). Precipitation can vary within the study area but the variation is minimized by the larger contribution from irrigation.

2.3.2. Topography

Topography in DRASTIC is the land surface's slope and slope variability. A pollutant is less likely to infiltrate into the soil when the land surface is more sloped. Steeper slopes also generally signify higher groundwater velocity.

Topography is not included in this evaluation. Topography in DRASTIC refers to slope and slope variability on a large scale of a regional area, which can influence the overall infiltration rate. But for this study, recycled water infiltration is more affected by local topography of each landscaped site. Higher infiltration of recycled water occurs in small-scale low points in the site topography. However, this level of detail for topography is not available as GIS data, nor is it practical to assemble data at this scale. Topography at this level can also be modified by property owners during construction activities, so it cannot be considered constant.

In addition, Title 22 regulations for recycled water use prohibit any runoff of recycled water from the recycled water use area, unless the runoff does not pose a public health threat and is authorized by the regulatory agency (Title 22, §60310 (e)). Therefore, large-scale topography would not have a significant impact on recycled water infiltration.

2.3.3. Aquifer Media and Hydraulic Conductivity of Aquifer

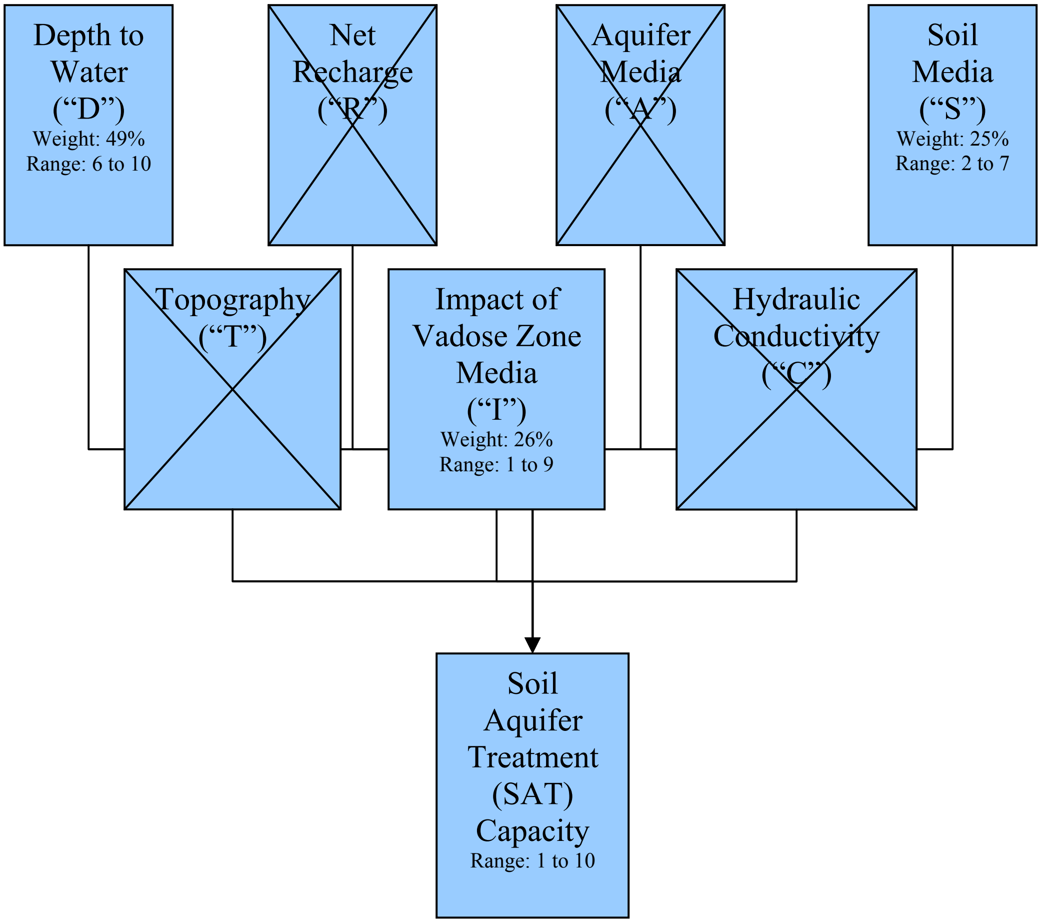
The aquifer media refers to the consistency of the porous material comprising the aquifer. Attenuative processes that can take place in the aquifer include sorption, transformation, and dispersion. The media of the aquifer determines the flow path and path length which in turn determines amount of time for attenuation. Larger grain sizes of the aquifer media correspond with higher porosity, which generally leads to higher permeability. Aquifers with high permeability are associated with lower attenuation capacity due to the decrease in soil contact time, which reduces any potential attenuation and increases potential for a contaminant to migrate quickly. Aquifer media also influences attenuation due to the effective surface area of the media.

The hydraulic conductivity of the aquifer refers to the permeability of the aquifer. For a given hydraulic gradient and hydraulic conductivity, the groundwater flow rate can be determined. Higher values of hydraulic conductivity are associated with lesser soil aquifer treatment capacity due to less time within the aquifer for attenuative processes to occur and greater potential for contaminants to travel. Attenuative processes that can take place in the aquifer include sorption, transformation and dispersion.

Aquifer media and hydraulic conductivity of aquifer are not included in this evaluation. Both of these inputs are criteria associated with treatment within the aquifer. Since the focus of this evaluation is the attenuative capacity before reaching groundwater, aquifer-related attenuation is not considered.

2.4. Weighting and Rating System Flowchart

The evaluation system comprises three factors each assigned a rating which can range from 1 to 10. Each factor is also weighted by a percentage based on the importance of the factor evaluated. The numerical evaluation allows for comparison of different areas for recycled water use in irrigation. Below is a flow chart of the variables used to determine SAT capacity.



Notes:
1) The seven factors above are the original DRASTIC inputs. Four of these factors are crossed indicating that they are not used in evaluating the SAT capacity.
2) Weight is the weighting or contribution assigned to the factor in determining the SAT capacity.
3) Range is the set of values that are valid for the factor or SAT capacity.

2.5. Calibration of Input Weightings

To determine the weighting of each input into the modified DRASTIC evaluation, the soil attenuation model from Volume II was used. A baseline scenario was used in the model to represent average conditions observed within the study area. Modifications were made individually to one of the evaluated model inputs (depth to water, soil media, and vadose zone media) to determine the net effect of that input on the modeled groundwater concentrations.

For the baseline scenario, the depth to groundwater was 40 feet (12.2 meters), with the first 6.6 feet (2 meters) defined as the soil media and the remaining soil profile as the vadose zone. The depth to groundwater of 40 feet is a median value for the study area, where it ranges from 0 to 100 feet. Silt was used as the baseline soil type for soil media and vadose zone. Silt is also a median value given the range of soil types observed in the study area. Attenuation levels were evaluated at the 40 foot depth and at the 50-year time frame. Chloroform was used as the constituent modeled. Chloroform, as seen in the soil attenuation model in Volume II, behaved in a manner that was consistent with the bench test and pilot study findings.

Using the base conditions as a starting point, the model inputs were then adjusted to determine differences in attenuation resulting from those changes. The core concept of this calibration is that relative to each factor, the weighting is proportional to the change in attenuation per unit change in rating. An alternative way this can be stated is the weighted change in rating per unit change in attenuation from each input contributes equally to the soil aquifer treatment capacity. Mathematically, this can be expressed as:

$$\frac{W_D \times \Delta\text{Rating}_D}{\Delta\text{Attenuation}_D} = \frac{W_S \times \Delta\text{Rating}_S}{\Delta\text{Attenuation}_S} = \frac{W_I \times \Delta\text{Rating}_I}{\Delta\text{Attenuation}_I}$$

and

$$W_D + W_S + W_I = 100\%$$

Where:

W = percent weight of input.
ΔRating = change in rating of input.
ΔAttenuation = change in attenuation of input.
D = depth to groundwater input. (discussed in Section 2.2.1)
S = soil media input. (discussed in Section 2.2.4)
I = impact of vadose zone media input. (discussed in Section 2.2.6)

Following these equations, the weighting of each input was determined using the modeled changes in attenuation caused by fixed changes in inputs. For the depth to groundwater input, the calibration used the attenuation difference from the 40 foot depth to the 5 foot depth. For the soil media, the calibration used the attenuation differences from silt to clay. For the impact of vadose zone media, the calibration used the attenuation differences from silt (silt loam was the appropriate category for this input) to clay.

The calibration determined the relative weighting of depth to groundwater, soil media, and impact to vadose zone to be 49%, 25%, and 26% respectively. Calculations and results of the calibration are displayed in Table IV-2-4. Graphs from the soil attenuation model used to determine the attenuation achieved are displayed in Figures IV-2-8 to IV-2-10.

2.6. Soil Aquifer Treatment Capacity Zones

Using the ratings and weighting factors discussed above, the relative soil aquifer treatment capacity is calculated as follows:

$$
\begin{aligned}
\left[\text{Soil Aquifer Treatment Capacity}\right] = {} & \left[\text{Weighting Factor for Depth to Water}\right] \times \left[\text{Depth to Water Rating}\right] + \\
& \left[\text{Weighting Factor for Soil Media}\right] \times \left[\text{Soil Media Rating}\right] + \\
& \left[\text{Weighting Factor for Impact to Vadose Zone}\right] \times \left[\text{Impact to Vadose Zone Rating}\right]
\end{aligned}
$$

After the calculation using the above equation, the values are rescaled such that the worst capacity found in the study area is set to 10 and the best capacity found in the study area is set 1. The unscaled range was found to be from 3.7 to 8.21. The net distribution of soil aquifer treatment capacity for the Santa Clara and Llagas Groundwater Subbasins are shown on Figures IV-2-11 and IV-2-12. The following is a description of the rating of the soil aquifer treatment capacity.

1 to 2 – High Capacity

A rating of 1 or 2 denotes areas with the highest capacity to attenuate constituents of recycled water relative to the range of hydrogeological conditions in the evaluation. These areas contain physical characteristics that are most ideal for the application of recycled water and protection of groundwater sources.

3 to 4 – Good Capacity

A rating of 3 or 4 denotes areas with good capacity to attenuate constituents of recycled water relative to the range of hydrogeological conditions in the evaluation. These areas contain physical characteristics that provide reasonably good capacity for soil aquifer treatment of recycled water constituents.

5 to 6 - Average Capacity

A rating of 5 or 6 denotes areas with average capacity to attenuate constituents of recycled water relative to the range of hydrogeological conditions in the evaluation. These areas contain physical characteristics that may provide some capacity for soil aquifer treatment of recycled water constituents.

7 to 8 - Marginal Capacity

A rating of 7 or 8 denotes areas with marginal capacity to attenuate constituents of recycled water relative to the range of hydrogeological conditions in the evaluation. These areas contain physical characteristics that have less capacity for soil aquifer treatment of recycled water constituents.

9 to 10 - Least Capacity

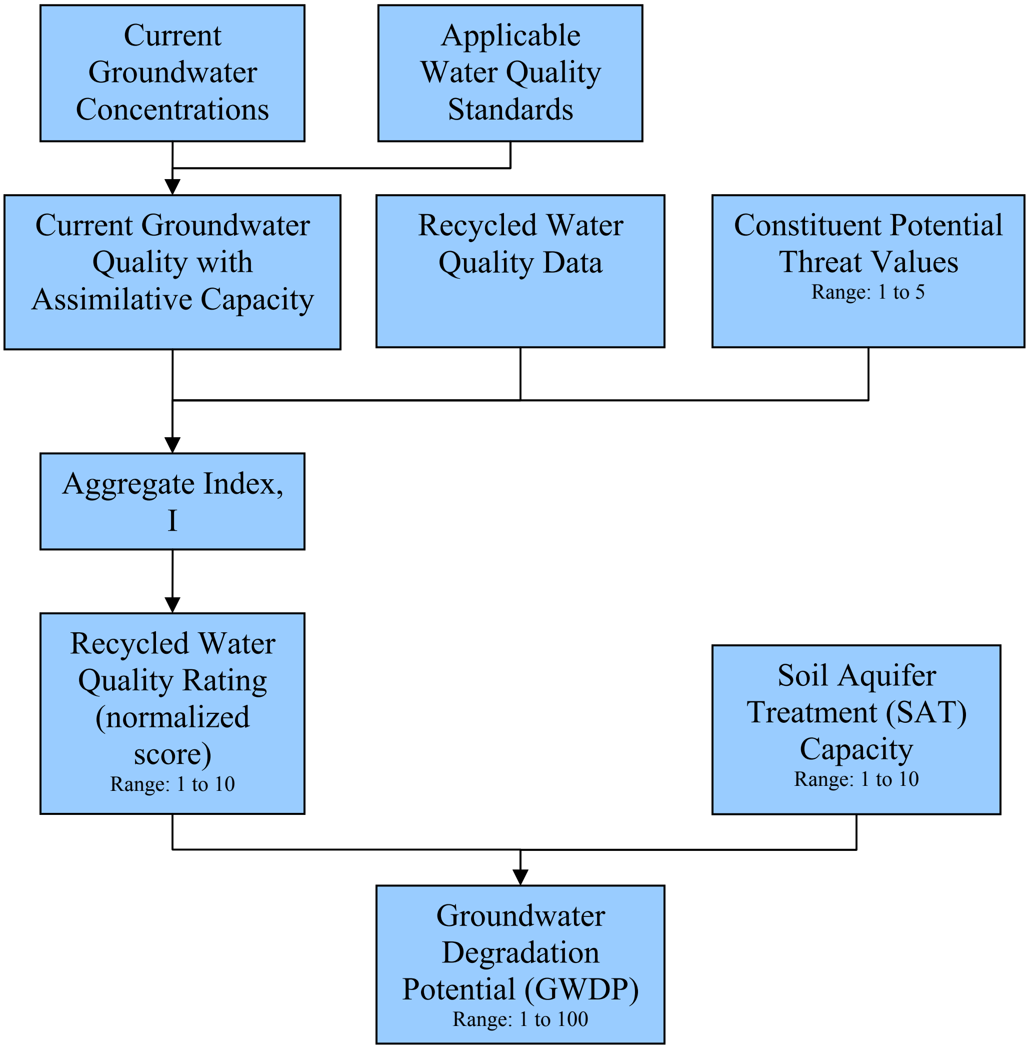
A rating of 9 or 10 denotes areas with the least capacity to attenuate constituents of recycled water relative to the range of hydrogeological conditions in the evaluation. These areas contain physical characteristics that are least ideal for soil aquifer treatment of recycled water constituents.

3. POTENTIAL TO DEGRADE GROUNDWATER QUALITY

Chapter 3 describes the methodology to determine the potential for recycled water as an irrigation source to degrade groundwater quality. The evaluation to determine the potential to degrade groundwater quality is directly related to the soil aquifer treatment capacity but also includes consideration of the quality of the recycled water.

3.1. Methodology

Methodology for determining groundwater degradation potential is a multiplicative rather than an additive approach of ratings from two evaluation criteria. The evaluation incorporates two inputs: 1) the soil aquifer treatment capacity, discussed in Chapter 2, and 2) the quality of the recycled water used for irrigation. The multiplication of these two ratings provides a range of the groundwater degradation potential up to maximum value of 100. This potential is calculated by multiplying the ratings so that a low rating in either input (meaning either excellent soil aquifer treatment capacity or very high quality recycled water), would result in relatively low groundwater degradation potential. Conversely, higher ratings for both inputs would cause a synergistic effect with significantly increased degradation potential if soil aquifer treatment capacity and recycled water quality are both low. Below is a flow chart of the variables used to determine the groundwater degradation potential.



Current Groundwater Concentrations
Applicable Water Quality Standards
Current Groundwater Quality with Assimilative Capacity
Recycled Water Quality Data
Constituent Potential Threat Values
Range: 1 to 5
Aggregate Index, I
Recycled Water Quality Rating (normalized score)
Range: 1 to 10
Soil Aquifer Treatment (SAT) Capacity
Range: 1 to 10
Groundwater Degradation Potential (GWDP)
Range: 1 to 100

3.2. Evaluation Criteria

3.2.1. Soil Aquifer Treatment Capacity

Soil aquifer treatment capacity was determined from Chapter 2 of this volume. SAT capacity incorporates hydrogeological parameters to rate the ability to attenuate recycled water constituents. Soil aquifer capacity rating ranges from one to ten, ten being the worst in terms of soil aquifer treatment capacity. The soil aquifer treatment capacity is a key input for evaluating the potential for recycled water to degrade groundwater quality.

3.2.2. *Recycled Water Quality Rating*

The recycled water quality is a necessary input for determining the groundwater degradation potential. Soil aquifer treatment capacity does not include consideration of the quality of the recycled water applied. Quality is dependent on the concentrations of the constituents found in the recycled water. Generally, the higher the quality of water of a given source is, the less potential for groundwater to be degraded. Groundwater is regarded as degraded when the quality becomes worse than the current groundwater quality, with consideration of assimilative capacity. For the constituents evaluated in this study, this would occur if the concentrations in groundwater increase from current values beyond the available assimilative capacity.

Because recycled water quality is represented by a range of constituents, there is a need to develop an aggregate water quality rating that can be calculated from the available concentration data for each recycled water source. The rating of the recycled water quality is determined using three types of information: 1) current groundwater quality in the study area, 2) the concentrations in recycled water, and 3) the relative threat of each constituent determined in Volume III of this study.

3.2.2.1. *Current Groundwater Quality*

Current groundwater quality is important in considering potential for groundwater degradation. For this study, mean groundwater concentration data and the assimilative capacity are used to represent the groundwater quality of the study area.

3.2.2.1.1.Groundwater Concentrations

Data used in this evaluation for groundwater quality was derived from SCVWD's database, and included data from 1973 to 2007. Additional data from the California Groundwater Ambient Monitoring and Assessment (GAMA) program (Ray et. al., 2009) and the pilot study baseline data from Volume III were also included to supplement SCVWD data. Statistics of the resulting dataset are found in Table IV-3-2.

For constituents with less than fifty available records in the SCVWD database, available data from the California GAMA program and pilot study were used. For the GAMA program, only data from wells located in the Santa Clara County were extracted. Where the accumulated data set is sufficient to quantify separate mean groundwater concentrations for Santa Clara and Llagas Groundwater Subbasins, the mean groundwater concentration is calculated separately for each subbasin. If the data set for a given constituent has less than 10 records for either groundwater subbasin, the mean groundwater concentration for the entire study area is used for both subbasins.

For the purpose of calculating mean groundwater concentrations, values below the reporting limit (nondetects) are taken as a value of zero. Using this approach, the mean concentration for a constituent may be less than the reporting limit. Where this occurs, the representative groundwater quality is taken to be the reporting limit. Table IV-3-2 contains the typical reporting limits, which are based on the data from the bench test and pilot study. The representative groundwater concentrations used for this evaluation are also listed on Table IV-3-2.

For biological parameters E. Coli, fecal, and total coliforms, the data is presented as frequency of detection rather than mean value. Frequency of detection was considered to be a more appropriate value for this evaluation than the mean value, because it is used frequently for water quality standards. Biological parameters are inherently different from the other constituents in recycled water and are evaluated in a different manner.

3.2.2.1.2.Assimilative Capacity

Assimilative capacity refers to the capacity of groundwater to receive pollutants without reducing the beneficial use (California SWRCB, 2009). For landscape irrigation projects using recycled water, the SWRCB states that the assimilative capacity is to be estimated by the project proponent and a salt and nutrient management plan is to be prepared. In the absence of a specific salt and nutrient management plan for the study area, the calculation of assimilative capacity for this study is as defined by SWRCB for groundwater recharge projects. Numerically, assimilative capacity for recharge projects is the difference between the mineral water quality objective and the average groundwater concentration of the subbasin, over the most recent five years of data available. The mineral water quality objectives are limits of acceptable water quality for beneficial use. If the current groundwater quality is better than the water quality objectives then there is assimilative capacity.

For this evaluation, water quality objectives are compiled using various regulatory standards and guidelines in the following order of priority:

- California Primary Maximum Contaminant Level (MCL)
- Federal Primary Maximum Contaminant Level (MCL)
- Federal Secondary Maximum Contaminant Level (MCL)
- Department of Public Health Notification Level
- Public Health Goal (CA OEHHA)
- EPA's Maximum Contaminant Level Goal
- EPA Health Advisory

These values for recycled water constituents are shown on Table IV-3-1. Where a limit for a given constituent is specified by multiple standards, the standard with the higher priority takes precedence. This means that the water quality objective is not necessarily the lowest limit found among the list of standards and guidelines. The calculation of assimilative capacity using the groundwater concentrations and water quality standards is shown on Table IV-3-1. Where the groundwater concentration is greater or equal to the water quality standard, the assimilative capacity is zero.

For consistency with the SWRCB Recycled Water Policy (SWRCB, 2009), this evaluation allows the use of up to 20 percent of the available assimilative capacity by multiple landscape irrigation projects. Calculations of representative groundwater concentrations with 20 percent of the available assimilative capacity are shown in Table IV-3-1.

3.2.2.2. Recycled Water Quality Data

Recycled water data is needed to measure the relative quality of the water against the representative groundwater quality. Water quality data of the recycled water from the four treatment plants can be found in the *Literature Review and Data Analysis* (Volume I of this report). Summarized data, ranging from 2001 to 2007, of the recycled water constituents from the four treatment plants are shown in Table IV-3-2. Mean data are calculated from sample sizes ranging from 1 to 21 samples. Appendix IV-A includes plot summaries of the available recycled water quality data and conveys the differences in recycled water quality between the four treatment plants. Data for the SJSC WPCP and SCRWA is also supplemented with data from the pilot study and bench test documented in Volume II and III. To be consistent with the calculation of representative groundwater concentration, as discussed in Section 3.2.2.1, nondetect values are evaluated as zero for the purpose of calculating mean recycled water concentrations.

The concentrations of recycled water constituents vary between different sources. Within the subbasins, recycled water is derived from four sources: the Palo Alto Regional Water Quality Control Plant (PARWQCP), Sunnyvale Water Pollution Control Plant (SWPCP), San Jose/Santa Clara Water Pollution Control Plant (SJ/SC WPCP), and the South County Regional Wastewater Authority (SCRWA). Current use of recycled water is geographically limited and thus recycled water is not used everywhere in the subbasins. To identify the potential for degradation throughout the subbasins, the study hypothetically assumes that recycled water is used everywhere in the subbasins. Because there are multiple sources of recycled water, the study uses city boundaries to distinguish which sources of recycled water could be applied in each area. SCRWA is hypothetically assumed to provide recycled water to the Llagas Subbasin which includes the cities of Gilroy and Morgan Hill and all unincorporated areas. Currently, SCRWA recycled water customers are within a small area of the Llagas Subbasin. In the Santa Clara Subbasin, recycled water is assumed to be largely derived from SJ/SC WPCP and to a lesser degree from PARWQCP and SWPCP. This evaluation assumes the city of Palo Alto and Stanford University receive recycled water from the PARWQCP. In Sunnyvale, Mountain View, Los Altos, and Los Altos Hills, recycled water is assumed to originate from SWPCP. Other cities within the Santa Clara Subbasin, including San Jose, Santa Clara, Milpitas, Campbell, Cupertino, Los Gatos, Saratoga, and Monte Sereno are assumed to receive recycled water from the SJ/SC WPCP. The assumed potential distribution of recycled water sources is shown on Figures IV-3-1 and IV-3-2 for both groundwater basins.

For the SWPCP and PARWQCP, not all constituent concentration data are available for these recycled water sources. Where this occurs, mean concentration values from the SJ/SC WPCP are used as a surrogate. While SJ/SC WPCP services a much larger area which includes more industrial activity than the area served by SWPCP and PARWQCP, the treatment trains at the three plants are similar. Therefore, the SJ/SC WPCP recycled water concentrations provide a reasonable surrogate for SWPCP and PARWQCP recycled water concentrations if actual concentration data are not available. Values should be replaced with actual measured concentrations if they become available. However, there are only a few constituents where this assumption needed to be applied, and the overall impact on the results of the evaluation is expected to be relatively minor. The values where this was applied can be seen in Table IV-3-2 where the count for the data is reported as zero.

3.2.2.3. Threat Values

The threat value for each constituent was determined in the *San Jose Pilot Study* (Volume III) and is displayed in Table IV-3-2. The threat to groundwater of each constituent of concern is based on the findings from the pilot study and the bench test. The threats range from 1 to 5, with 5 representing the highest relative threat. The criteria for assigning each threat are generally determined on the observed attenuation of the constituent in the pilot study and bench test, and the type of constituent. The type of constituent can range from general water quality parameters like alkalinity and DO, to emerging contaminants like NDMA and PFCs. The potential health impact of each constituent is also evaluated in assigning the threat. The threat assigned for each constituent below is a combination of these factors. For constituents where behavior was not well observed due to a low occurrence in the source water, a threat of three was assigned. This central value is selected to indicate that although the low occurrence in recycled water may result in lower potential to impact groundwater, the potential for this constituent to migrate to groundwater may be significant if present.

A low threat indicates that the given constituent has shown minimal potential to impact groundwater in the pilot study. A higher threat indicates that the constituent in recycled water has shown significant potential to impact groundwater and may need to be taken into consideration in future recycled water irrigation use.

Some monitored constituents were not consistently detected in the recycled water source during the pilot study or bench test; therefore the threat of these constituents was regarded as inconclusive. Constituents that fall into this category include E. Coli, nitrilotriacetic acid (NTA), perchlorate, cyanide, and terbuthylazine. For the evaluation purposes of determining recycled water quality in Volume IV, the constituents with inconclusive determinations are assigned a default threat of 3, which is an average value within the 1 to 5 threat range. This default value may be reassigned to a more appropriate value if further studies provide provide more information on the potential threat of a given constituent.

3.2.2.4. Calculation Method

The above three factors, current groundwater quality with assimilative capacity (Section 3.2.2.1), recycled water concentrations (Section 3.2.2.2), and threat (Section 3.2.2.3), are used to calculate the recycled water quality rating. The method for determining recycled water quality follows a published aggregation index method (Swamee and Tyagi, 2000 and 2007). The aggregation method aims to avoid ambiguity, eclipsing, and rigidity issues. Ambiguity issues occur when all subindices indicate acceptable water quality, but the aggregate index does not. Eclipsing issues occur when the aggregated index fails to reflect poor water quality of one or more of the water quality variables. Rigidity issues occur when the aggregation function does not allow for new variables to be added to the aggregated index. All of these issues are minimized by the applied aggregation method described below.

The aggregation index, I, can be expressed as:

$$I = \left(1 - N + \sum_{i=1}^{N} s_i^{-1/k}\right)^{-k}$$

Where:

I = Aggregate index of the recycled water quality.

N = Number of subindices considered. In this study, the number of subindices corresponds to the number of constituents evaluated in this method (N=39).

s = Subindex for the individual constituent (calculated as described below).

k = Aggregation exponent, derived as $k = \frac{1}{\log_2(N-1)}$ using an assigned central value for the aggregate index (Swamee, 2007).

The subindices are based on the constituent concentrations, and can be calculated using several methods. For subindices that monotonically decrease with their water quality concentrations, Swamee and Tyagi (2000) recommend the following equation. This equation is recommended as the most appropriate when water quality is consistently considered lower for higher concentrations.

$$s = \left(1 + \frac{q}{q_c}\right)^{-m}$$

Where:

q = Quality of the constituent, which is taken to be the difference between the constituent concentration in recycled water and q_c. q is set to zero if the recycled water concentration is lower than q_c.

q_c = Representative groundwater quality, which is the current groundwater concentration of the given subbasin with 20 percent of the available assimilative capacity as calculated in Table IV-3-1.

m = Subindex exponent.

The subindex exponent, m, varies for each constituent, and it reflects the contribution of the constituent subindex to the overall aggregate index, I. For the purpose of this study, the subindex exponents were correlated to the threat of each constituent, as determined in Volume III (see Section 3.2.2.3). The appropriate distribution for this value was determined to be a positively-correlated function (i.e. increasing threat values cause an increasing impact to the aggregate index). Constituents assigned a threat of 1 should have a negligible effect on the aggregate index. Constituents assigned a threat of 5 should have the most significant effect on the aggregate index.

Using a polynomial distribution, the following function is derived for the subindex exponent:

$$m = [\text{threat}] \times ([\text{threat}] - 1) \times [\text{mscale}].$$

Using this equation, the value for mscale was determined by maximizing the range in aggregate scores between the four recycled water sources. The aggregate indices converge to the same value for high or low values of mscale. For this evaluation, the difference between the aggregate indices was maximized in order to best demonstrate the quality differences between the recycled water sources. The optimized value for mscale was 0.021218. The derivation of this value is shown in Figure IV-3-5.

Per Swamee, the resulting aggregate index, I, ranges from 0 to 1 such that 1 is indicative of high quality water and 0 is indicative of poor water quality. To refit the index for the needs of this study, a modified aggregate index, 1-I (i.e. one minus the aggregate index) is used to represent higher water quality with a decreasing numerical value. The modified aggregate index is rescaled on a range from 1 to 10 using the modified aggregate index of the representative groundwater quality and maximum observed recycled water quality as the minimum and maximum boundary conditions.

Recycled water quality ratings are determined for the recycled water from the four treatment plants in the study area. The results of this calculation are summarized below. Table IV-3-3 summarizes the calculations and results with greater detail.

Parameter	PARWQCP	SCRWA	SJ/SC WPCP	SWPCP
Aggregate Index, I (per Swamee)	0.16	0.37	0.16	0.31
Modified Aggregate Index, 1 – I	0.84	0.63	0.84	0.69
Recycled Water Quality	9.61	7.45	9.63	8.08

Not all constituents were included in the calculation of the recycled water quality ratings. Total alkalinity, bicarbonate alkalinity, dissolved oxygen, total chlorine, oxidation reduction potential, and pH are general water quality parameters and are not included in the analysis. To avoid double counting, total dissolved solids (TDS) was not included in the analysis because TDS is the sum of other constituents that are already included in the evaluation. Heterotrophic plate count was excluded because the accuracy of that analysis makes use of those values unsuitable for quantifying comparisons between water sources.

3.3. Assumptions

Because the pilot study threat values were determined based on conditions at the IDT site (including the site's landscape irrigation), the groundwater degradation potential evaluation assumes similar conditions as the pilot study, including the irrigation rate. Irrigation for general landscape is assumed for this evaluation. General landscaping includes turf grass and small shrubs, which are most common through the study area. The rate of irrigation at the pilot study site was 38.7 inches per year and is similar to the recommended application rate for the site (ITAP, 2006). Landscaping that requires irrigation with a different annual application rate (i.e. vegetation that have greater or lesser water needs) may change the potential to degrade groundwater. Generally, less irrigation with recycled water means less potential for groundwater degradation and more irrigation with recycled water means more potential for groundwater degradation.

3.4. Zones

Groundwater degradation potential is calculated using the inputs described above as follows:

[Groundwater Degradation Potential] = [Soil Aquifer Treatment Capacity] × [Recycled Water Quality Rating]

The net distribution of the relative rating for groundwater degradation potential for the Santa Clara and Llagas Groundwater Subbasins are shown on Figures IV-3-3 and IV-3-4. The following is a description of the relative ratings of the groundwater degradation potential.

1 to 20 – Lowest Potential

A rating of 1 to 20 denotes areas with the least potential for recycled water application to degrade groundwater relative to the range of hydrogeological conditions and recycled water qualities in the study area. The combination of the area's physical characteristics and the local recycled water source is ideal for irrigation using recycled water.

21 to 40 – Low Potential

A rating of 21 to 40 denotes areas with low potential for recycled water application to degrade groundwater relative to the range of hydrogeological conditions and recycled water qualities in the study area. These areas contain characteristics that provide reasonably good capacity for soil aquifer treatment of recycled water constituents of the given local recycled water source. The potential for recycled water to impact groundwater in these areas is comparatively low.

41 to 60 - Average Potential

A rating of 41 to 60 denotes areas with average potential for recycled water application to degrade groundwater relative to the range of hydrogeological conditions and recycled water qualities in the study area. These areas contain characteristics that may provide some capacity for soil aquifer treatment of recycled water constituents of the local source. However, there is potential for groundwater to be impacted by some recycled water constituents.

61 to 80 – High Potential

A rating of 61 to 80 denotes areas with significant potential for recycled water application to degrade groundwater relative to the range of hydrogeological conditions and recycled water qualities in the study area. These areas contain characteristics that have relatively marginal capacity for soil aquifer treatment and/or a relatively high concentration of constituents of the local recycled water. There is likelihood of one or more recycled water constituents impacting groundwater in these areas.

81 to 100 – Highest Potential

A relative rating of 81 to 100 denotes areas with the greatest potential for recycled water application to degrade groundwater relative to the range of hydrogeological conditions and recycled water qualities in the study area. These areas contain characteristics that are least ideal for soil aquifer treatment and/or likely have a high concentration of constituents of the local recycled water. Potential for recycled water constituents to impact groundwater sources is regarded as highest.

3.5. Limitations

Development of the zones for the potential to degrade groundwater is specific to current recycled water quality from the PARWQCP, SWPCP, SJ/SC WPCP, and SCRWA treatment plants. With the exception of the data collected during this study, the current recycled water quality data span from 2001 to 2007. Changes in recycled water quality, whether improved or worsened, will affect the groundwater degradation potential of recycled water application. Changes in recycled water quality can be caused by a switch to a different local recycled water source, modification of the treatment plant process, or change in quality of the received wastewater.

Threat values for this study were determined for each recycled water constituent based on available data from the bench test and pilot study. Both of those investigations had limitations in how they represent various physical conditions and long-term fate and transport of recycled water constituents. Those limitations are discussed in Volumes II and III of this report. Additional long-term monitoring under other site conditions may reveal that some constituents are more or less of a threat compared to what was concluded from the bench test and pilot study. Revisions to the threat levels would affect the overall recycled water scores and hence the groundwater degradation potential.

Development of the potential groundwater degradation zones is reliant on constituents with current and available data and information. For constituents with only a handful of sample data, the evaluation can be strengthened with ongoing monitoring for either recycled water or groundwater. Both recycled water and groundwater concentrations are used to derive the recycled water scores. In addition, there is the possibility of new contaminants which are not yet identified. As new contaminants are discovered, this analysis can be updated to reflect the groundwater degradation potential introduced by the new contaminant.

4. DISCUSSION

4.1. Soil Aquifer Treatment Capacity

Soil Aquifer Treatment (SAT) capacity maps are found in Figure IV-2-11 and IV-2-12 for the Santa Clara and Llagas Subbasin respectively. Based on a relative scale, the SAT rating in the Santa Clara Subbasin ranges from 1 to 10 (high to least capacity). In the Llagas Subbasin, the SAT rating ranges from 1 to 9.4. In both subbasins, the confined areas were determined to have relatively high capacity due to the confining layer and deep depth to groundwater. The unconfined areas were largely of good or average capacity. Only a few areas in the unconfined areas were regarded as having relatively marginal capacity and even fewer areas were regarded as least capacity. Areas with a lower rating tended to be characterized with shallow depth to water and a coarse grain size distribution in the vadose zone.

The SAT capacity map (Figure IV-2-11) shows a value of 5 for the IDT site, which indicates average SAT capacity. For comparison, direct calculation of the SAT capacity at the IDT site using site-specific data gives a rating of 2.5, indicating relatively good treatment capacity, which corresponds well with the findings from the pilot study. IDT has an approximate depth to groundwater of 35 feet (D = 7.0). The soil media and vadose zone media at IDT site is uniformly clay (S = 2, I = 2). A SAT rating of 2.5 is regarded as good capacity where the physical characteristics of the area provide good capacity for attenuation of recycled water constituents. This corresponds with the pilot study findings, which showed that there was reasonably good attenuation across depth for several constituents during the pilot study period. However, there were a few recycled water constituents that showed low concentrations in the groundwater, indicating that conditions were not ideal for recycled water application. The pilot study findings support the SAT rating, verifying the appropriateness of the methodology. The SAT values calculated using site-specific data (2.5) and the regional averaged approach (5) do not match exactly because the SAT capacity maps used basin-wide data to evaluate areas on a larger scale. The SAT capacity maps may not capture site-specific detail, however they provide a general indication of the SAT capacity for the area. These maps can be refined to reflect site-specific information as more data becomes available.

4.2. Groundwater Degradation Potential

Groundwater degradation potential maps are found in Figures IV-3-3 and IV-3-4 for the Santa Clara and Llagas Subbasin respectively. Groundwater degradation potential in the Santa Clara Subbasin is largely of lowest to average potential with a few areas regarded as high or highest. The rating in the Santa Clara Subbasin ranges from 8 to 96. Groundwater degradation potential in the Llagas Subbasin is largely of lowest to average potential and with a few areas regarded as high. The evaluation did not find any areas of the highest groundwater degradation potential in the Llagas Subbasin. In the Llagas Subbasin, the groundwater degradation potential rating ranges from 11 to 70. Comparatively, the Santa Clara and Llagas Subbasins share a similar distribution in groundwater degradation potential with a majority of lowest and low potential found in the confined areas and more average potential in the unconfined areas.

The groundwater degradation potential map (Figure IV-3-3) shows a value of 48.9 for the IDT site, which indicates average groundwater degradation potential. For comparison, direct calculation of the groundwater degradation potential at the IDT site using site-specific data gives a rating of 24, which indicates low groundwater degradation potential and corresponds well with the findings from the pilot study. At the IDT site, the SAT capacity rating is calculated as 2.5 using site-specific data, indicating relatively good capacity. At the IDT site, the recycled water was derived from the SJ/SC WPCP which was determined to have a recycled water quality rating of 9.62. A groundwater degradation potential of 24 is regarded as low potential, but some potential exists for groundwater degradation. The rating agrees with the results of the pilot study. For the given recycled water quality from the SJ/SC WPCP, there was a significant number of constituents that appeared to exhibit removal with depth. However, a few constituents were observed in groundwater, indicating some potential to degrade groundwater long-term (18 months). Overall, the pilot study agrees with the rating of the groundwater degradation potential, verifying the appropriateness of the methodology. While the pilot study is complete, groundwater sampling at the pilot study site is ongoing. The evaluation made in this volume can be updated as ongoing monitoring yields new data.

Similar to SAT, the GWDP values calculated using site-specific data (24) and the regional averaged approach (48.9) do not match exactly.. The GWDP maps used basin-wide data to evaluate areas on a larger scale. The GWDP maps may not capture site-specific detail, however they provide a general indication of the GWDP for the area. As with the SAT maps, the GWDP maps can be refined to reflect site-specific information as more data becomes available.

4.3. Comparison to the Groundwater Vulnerability Study

While the goals of the Groundwater Vulnerability Study (SCVWD, 2010) and this study are uniquely different, there is some similarity in the approach and the input parameters. The vulnerability study examined the Santa Clara, Coyote, and Llagas Subbasins with the goal of evaluating the sensitivity and vulnerability of the groundwater. In the vulnerability study, groundwater sensitivity is defined as the relative ease with which a contaminant on or near the land surface can migrate to the aquifer of interest. Sensitivity is a function of the aquifer properties (i.e. hydraulic conductivity, porosity, and hydraulic gradient) and the associated sources of water and stresses to the groundwater system (i.e. recharge, travel through the unsaturated zone, and well pumping). Contrasting to the vulnerability study, the soil aquifer treatment capacity and groundwater degradation potential were evaluated in the context of expanding the use of recycled water for irrigation in the study area. The study looked specifically at constituents that are found in recycled water and irrigation was the main driver of vadose zone percolation.

The most similar evaluation to the SAT capacity is the sensitivity assessment from the vulnerability study. Input parameters for the sensitivity assessment included (1) soil media characteristics in the vadose zone, (2) groundwater recharge, (3) depth to top of the aquifer, and (4) annual groundwater production. The SAT capacity assessment presented in this report did not include groundwater recharge or annual groundwater production. Groundwater recharge was omitted in the SAT capacity assessment because for the purpose of determining SAT capacity with respect to recycled water use, the main contributor to groundwater recharge is irrigation of recycled water. In the vulnerability study, the groundwater recharge component included both managed recharge and precipitation. Annual groundwater production was not evaluated for SAT capacity because the value is intended to represent attenuation within the vadose zone, as opposed to within the vadose zone and aquifer.

For the sensitivity of the principal aquifer, the Groundwater Vulnerability Study determined that the sensitivity was nine and ten (high) in the majority of the Llagas Subbasin. In the Santa Clara Subbasin, the sensitivity ranged from one (low) to nine. The northern most section of the subbasin was regarded as low sensitivity. The most sensitive areas within the Santa Clara Subbasin are the western side of the confined area and portions of the unconfined areas. Comparing the two subbasins, the vulnerability study determined that the Llagas Subbasin was more sensitive than the Santa Clara Subbasin. The soil aquifer treatment map indicates the highest capacity for SAT in the confined areas in both subbasins. The Llagas subbasin generally did not have less SAT capacity than the Santa Clara Subbasin. Variation between the maps from the two studies may be attributed to the differences in the input parameters (i.e. groundwater recharge and groundwater production) used and the difference in the goal of the respective study. The Groundwater Vulnerability Study assessed general groundwater sensitivity to contaminants while the goal of this study is to assess the degradation potential of groundwater specifically from recycled water use as an irrigation source.

5. CONCLUSION

Using a developed and calibrated methodology, and data collected from previous phases of the study, values of soil aquifer treatment capacity and groundwater degradation potential were calculated for the entire study area.

Soil aquifer treatment in the Santa Clara and Llagas Subbasin ranged from least to high capacity. Areas with the highest relative SAT capacity were found to be in the confined areas in the Santa Clara Subbasin and in the Llagas Subbasin. The confining layer and deep depth to groundwater are characteristics of the best areas within the study area for soil aquifer treatment capacity.

Groundwater degradation potential in the Santa Clara and Llagas Subbasin ranged from lowest to highest potential. Groundwater degradation potential was found to be generally low or lowest in the confined areas. Groundwater degradation potential in the unconfined areas was found to be generally average with some areas regarded as high or highest.

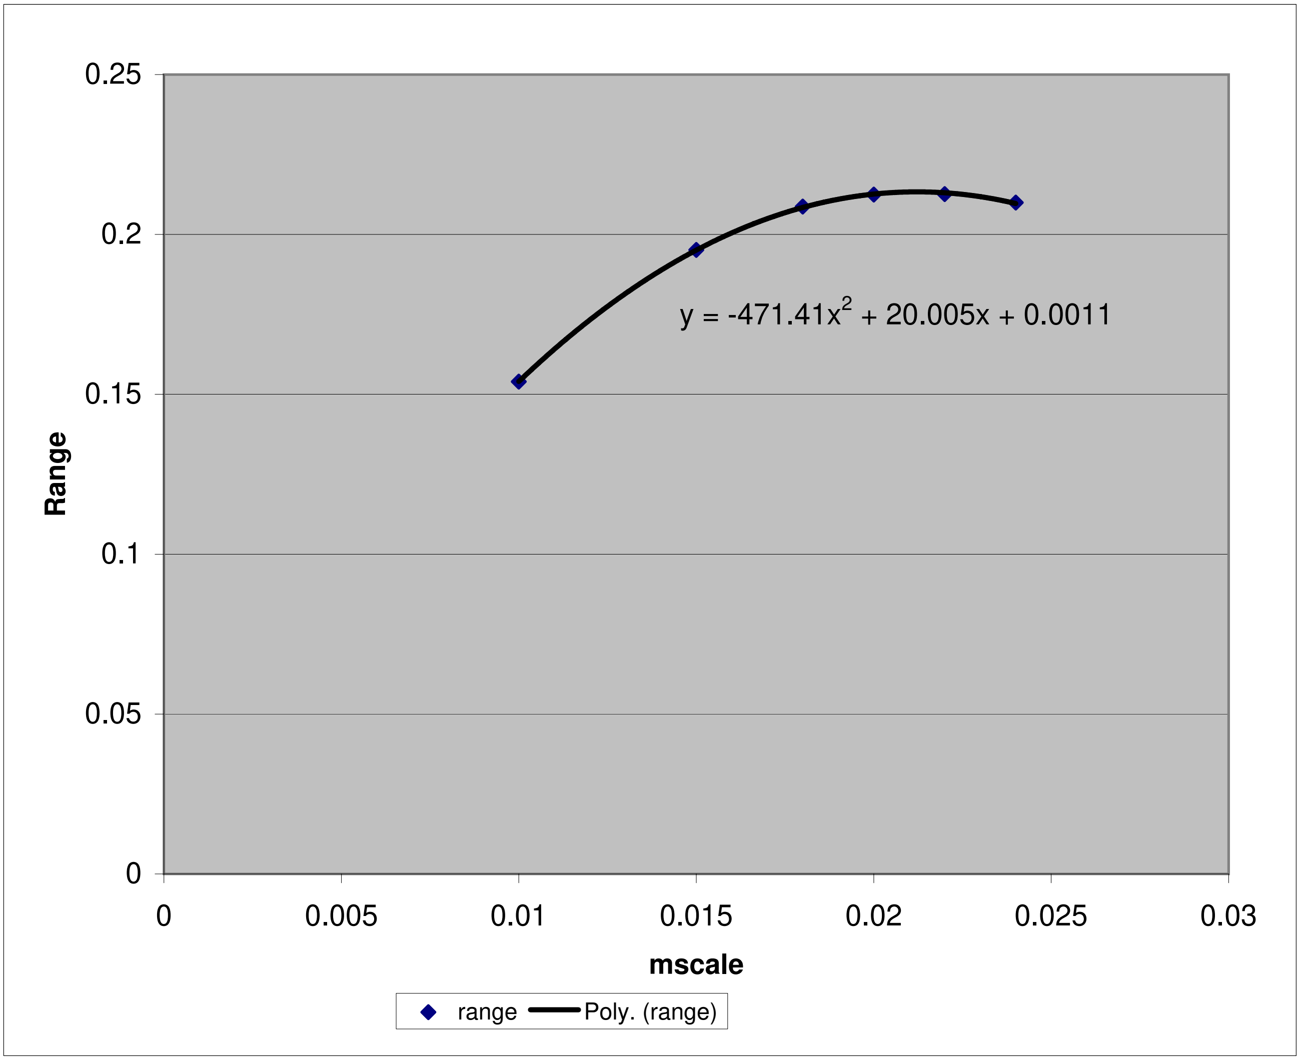
FIGURE IV-3-5
SUBINDEX EXPONENT DERIVATION



mscale value	Range in aggregate indices
0.01	0.153950982
0.015	0.195131597
0.018	0.20873943
0.02	0.212461682
0.022	0.212637299
0.024	0.209943724

Note:
The value of mscale was selected so that the difference between recycled water quality ratings (aggregate indices) would be maximized. The difference between the maximum and minimum aggregate indices was calculated for a range of mscale values as shown in the table above. With respect to mscale, the range varied according to a polynomial trend. The maximum range was observed at an mscale value of 0.021218.

TABLES

TABLE IV-2-1
DERIVATION OF RATINGS FOR DRASTIC DEPTH TO WATER INPUT

Parameter	Value	Comments
Total HAA6 concentration in Recycled Water Source	**6.35625** µg/L	Averaged over course of pilot study
Total HAA6 concentration at 5 feet	**1.53** µg/L	Average of two latest sampling events
Total HAA6 concentration at 10 feet	**0.835** µg/L	Average of two latest sampling events
Total HAA6 concentration at 30 feet	**0.0325** µg/L	Average of two latest sampling events
Percentage Removal at 5 feet	**75.9%**	
Percentage Removal at 10 feet	**86.9%**	
Percentage Removal at 30 feet	**99.5%**	
Ratio of 10-foot to 5-foot attenuation capacity	**1.144**	
Ratio of 30-foot to 5-foot attenuation capacity	**1.310**	
New DRASTIC Depth to Water Rating (5 feet)	**10**	
New DRASTIC Depth to Water Rating (10 feet)	**8.7**	
New DRASTIC Depth to Water Rating (30 feet)	**7.6**	

Sensitivity of Groundwater Data Point
[0.26 J ug/L for Monochloroacetic acid in MW-2 on the eighth sampling event]

Scenario 1: Substitute value for zero (0 ug/L)	Value	Comments
Total HAA6 concentration in Recycled Water Source	6.35625 µg/L	Averaged over course of pilot study
Total HAA6 concentration at 5 feet	1.53 µg/L	Average of two latest sampling events
Total HAA6 concentration at 10 feet	0.835 µg/L	Average of two latest sampling events
Total HAA6 concentration at 30 feet	**0** µg/L	Average of two latest sampling events
Percentage Removal at 5 feet	75.9%	
Percentage Removal at 10 feet	86.9%	
Percentage Removal at 30 feet	100.0%	
Ratio of 10-foot to 5-foot attenuation capacity	1.144	
Ratio of 30-foot to 5-foot attenuation capacity	1.317	
Scenario 1 DRASTIC Depth to Water Rating (5 feet)	10	No change in rating
Scenario 1 DRASTIC Depth to Water Rating (10 feet)	8.7	No change in rating
Scenario 1 DRASTIC Depth to Water Rating (30 feet)	7.6	No change in rating

Scenario 2: Substitute value for reporting limit (2 ug/L)	Value	Comments
Total HAA6 concentration in Recycled Water Source	6.35625 µg/L	Averaged over course of pilot study
Total HAA6 concentration at 5 feet	1.53 µg/L	Average of two latest sampling events
Total HAA6 concentration at 10 feet	0.835 µg/L	Average of two latest sampling events
Total HAA6 concentration at 30 feet	**0.25** µg/L	Average of two latest sampling events
Percentage Removal at 5 feet	75.9%	
Percentage Removal at 10 feet	86.9%	
Percentage Removal at 30 feet	96.1%	
Ratio of 10-foot to 5-foot attenuation capacity	1.144	
Ratio of 30-foot to 5-foot attenuation capacity	1.265	
Scenario 2 DRASTIC Depth to Water Rating (5 feet)	10	No change in rating
Scenario 2 DRASTIC Depth to Water Rating (10 feet)	8.7	No change in rating
Scenario 2 DRASTIC Depth to Water Rating (30 feet)	**7.9**	Slight increase in rating

Notes:

For the purpose of totalling HAA6 concentrations, haloacetic acid concentrations below detection were assumed to be zero.

TABLE IV-2-2
DERIVATION OF RATINGS FOR SOIL MEDIA AND IMPACT OF THE VADOSE ZONE MEDIA INPUTS

Soil Core	SCRWA-B	SCRWA-C	SCRWA-D	SJSC-C	SJSC-D	Comments
Core Description	semifine	coarse	fine (with gypsum)	coarse	fine (with gypsum)	
Core Length	4 feet	4 feet	1 foot	4 feet	1 foot	
Core Soil Type	silt w/sand	well-graded sand and gravel	clay w/sand	poorly graded gravel w/silt and sand	silty clay	
Default DRASTIC S Layer Classification	silty loam	sand loam to sand	massive clay	sand loam to sand	massive clay	
Default DRASTIC I Layer Classification	sand and gravel with significant silt and clay (silt end of this range)	sand and gravel (sand end of this range)	silt/clay (clay end of this range)	sand and gravel (sand end of this range)	silt/clay (clay end of this range)	
Customized I Layer Classification	Between silt and loam	sand	clay	sand	clay	
Total Trihalomethane Concentration Removal	78%	56%	67%	57%	71%	Based on comparison of last effluent sample with first influent sample.
Total Trihalomethane Concentration Removal (adjusted)	31%	18%	67%	19%	71%	Normalized to 1 foot
Ratio of Removal to Sand Removal	1.70	1.00	3.63	1.00	3.78	
New Assigned DRASTIC S Layer Rating	4.1	7	1.9	7	1.9	
New Assigned DRASTIC I Layer Rating	3.5	6	1.7	6	1.6

Notes:

1. Typical Reporting Limit from the bench test and pilot study data
2. For the purpose of calculating mean values, nondetects were evaluated as zero. "ND" is reported for the mean if all values are nondetect.
3. Basin-specific concentrations are used where there are a sufficient number of data to support quantification in each basin. Otherwise, the mean for the entire study area is applied to both basins. Where the groundwater data mean is below the typical reporting limit, the reporting limit was used. Additionally, 20 percent of the assimilative capacity as derived in Table 3-1 is included in these concentrations.
4. Total/Fecal Coliforms and E.Coli are presented in this table as frequency of detection rather than mean.
5. Heterotrophic plate count results were not used for this analysis, because there is limited accuracy with this analysis. Biologicals are adequately represented by the other biological parameters.
6. Mean values for recycled water sampled from each treatment plant. For PARWQCP and SWPCP where no data are available (count listed as 0), the concentration observed in SJSC WPCP is used as a surrogate.
7. Data includes groundwater data from the SCVWD database up to 2007, pilot study baseline, and the GAMA program.
8. Minimum and maximum is determined using data from all four treatment plant data.

NA - No data available.
Non-detects treated as zero concentration.
mg/L - milligrams per liter
µg/L - micrograms per liter
ng/L - nanograms per liter
MPN/100mL - most probable unit per 100 mL
CFU/mL - colony forming units per milliliter

EXECUTIVE SUMMARY

Volume V, prepared by Locus Technologies (Locus) on behalf of the Santa Clara Valley Water District (SCVWD), covers the final phase of the Recycled Water Irrigation and Groundwater Study. The overall goal of the study is to evaluate the potential impact to groundwater from expanded use of recycled water for irrigation in the Santa Clara and Llagas Subbasins (study area). The scope of this portion of the report is to establish guidance for the use of recycled water in irrigation in the study area in a manner that sustainably protects groundwater from this particular use. This includes the development of proposed recycled water irrigation screening levels (PRWISLs), best management practices (BMPs), and ongoing monitoring recommendations for recycled water and groundwater.

Proposed Recycled Water Irrigation Screening Levels

In conjunction with best management practices and ongoing monitoring recommendations, proposed recycled water irrigation screening levels (PRWISLs) are developed for recycled water irrigation aimed at protecting groundwater sources in the study area. The function of the PRWISLs is to provide guidance on threshold concentrations of constituents in recycled water for the given soil aquifer treatment (SAT) zone. For this study, the PRWISL is defined as the maximum concentration of a recycled water constituent for irrigation at which minimal groundwater degradation potential can be achieved.

Recycled water concentrations higher than the PRWISLs will always result in greater than minimal groundwater degradation potential. However, a recycled water quality that meets all the PRWISLs does not necessarily indicate minimal groundwater degradation potential because the PRWISL of each constituent assumes there is no contribution to the GWDP from the other constituents. To quantify the GWDP, the forward evaluation for determining the groundwater degradation potential as discussed in Volume IV must be performed.

PRWISLs vary within the study area based on the soil aquifer treatment capacity and representative groundwater quality. The PRWISLs also consider the constituent's threat level determined from the pilot study and bench test in previous phases of this study. To determine proposed recycled water irrigation screening levels for recycled water irrigation, an inverse calculation approach was used from the methodology developed for determining the groundwater degradation potential. By constraining the groundwater degradation potential to an assumed target maximum acceptable level, which is numerically 20 for the lowest groundwater degradation potential, an analysis can be performed to compute the maximum recycled water concentration for each constituent that will result in the target groundwater degradation potential. Proposed recycled water irrigation screening levels are shown in Table V-2-1 and are established for each soil aquifer treatment zone and subbasin.

Best Management Practices

Best management practices (BMPs) are recommendations to maintain optimal use of recycled water for irrigation while protecting groundwater. BMPs evaluated in this report are specific to recycled water use as an irrigation source for landscape with the goal of minimizing the degradation of groundwater resources. BMPs that may affect groundwater degradation potential with respect to recycled water include practices such as dilution, fertilizer application, site selection, irrigation optimization, and gypsum application. Dilution may be an appropriate measure for areas where the quality of the recycled water is above proposed recycled water irrigation screening levels. In addition, source control or modifications of treatment processes may also be options for reducing the groundwater degradation potential. Reduced fertilizer application can minimize potential impacts of migration of nutrients found in recycled water to groundwater. Careful selection of sites for recycled water application is important to avoid the mobilization of other contamination sources that may be present onsite. Optimizing the irrigation system minimizes the total volume of irrigation needed for application and consequently minimizes the mass load of recycled water constituents applied. Gypsum application can promote soil drainage which is important for maintenance of landscaping, as well as preventing water logging and possible runoff of recycled water to surface waters. However, it also accelerates migration of recycled water constituents to groundwater. Therefore, its use needs to be carefully balanced.

Ongoing Monitoring Recommendations

Recommendations for ongoing monitoring were developed to monitor the potential long term impacts to groundwater from use of recycled water for irrigation in the Santa Clara and Llagas Subbasins. The goal of the ongoing monitoring is to provide timely recognition of any adverse changes in groundwater quality due to application of recycled water. This monitoring schedule serves as a general guideline for monitoring activities. Future deviations from this monitoring schedule may be appropriate to optimize this program.

Site-specific data can be used to directly calculate the groundwater degradation potential to help determine if additional monitoring is needed. The use of this data, along with available groundwater monitoring results from areas with similar physical and recycled water quality characteristics may reduce the need for additional monitoring.

If additional monitoring is needed within the area of current or planned recycled water irrigation, the location of monitoring wells should be prioritized to areas of highest groundwater degradation potential as shown on Figures IV-3-3 and IV-3-4 of Volume IV of this report.

The following is a summary of proposed criteria for achieving adequate monitoring:

1) Select or install wells at or adjacent to sites where recycled water irrigation is implemented. Monitoring wells should be downgradient of the application area.

2) While not every irrigation site needs to be monitored, at least one should be monitored to represent each region of expansion with similar calculated GWDP values. If a region of expansion contains different rating categories of GWDP, consider monitoring an irrigation site in each unique subregion.

3) Monitoring wells located between application areas and production wells will be useful in monitoring water quality that may affect production.

4) Monitor for the groundwater of interest (i.e. in the principal aquifer) and in shallower aquifers. Shallower aquifers can provide an early indication of changes in water quality.

5) Avoid monitoring wells that are screened in multiple aquifers, since samples would effectively be an average groundwater concentration across multiple aquifers.

6) Use denser monitoring well spacing in areas of higher GWDP where groundwater degradation is most likely to occur.

Groundwater monitoring is recommended at the following frequency guideline, which also varies depending on the groundwater degradation potential. The monitoring frequencies were developed based on observations from the pilot study phase of this study.

Highest Groundwater Degradation Potential in Represented Area	Monitoring Frequency		
	Year 1	Year 2-4	Year 5 and beyond
1-20	Quarterly	Semi-annually in spring and fall	Annually in fall
21-40	Quarterly	Quarterly	Semi-annually in spring and fall
41-60	Monthly	Quarterly	Semi-annually in spring and fall
61-100	Monthly	Quarterly	Quarterly

After a period of monitoring events, if evaluation of the data demonstrates that the quality of groundwater has not degraded past 20 percent of the assimilative capacity and does not show an increasing trend, the groundwater monitoring scope may be reduced in frequency or in the number of wells monitored. The schedule is designed to allow for more frequent observations in the beginning of implementation of expanded use of recycled water. This ensures that if groundwater degradation occurs as a result of recycled water use, it will be detected early. Conversely, the monitoring scope can be increased in frequency or number of wells if adverse impacts are encountered.

Recycled water monitoring is recommended for wastewater treatment plants in order to verify that recycled water quality does not change over time. If recycled water quality worsens over time, additional measures, such as additional treatment, source control, or dilution as specified in the BMPs should be implemented in order to maintain the same level of groundwater protection. During this study, recycled water concentrations were observed to be relatively consistent over time when sampled at the same location. Annual monitoring of recycled water is recommended from each treatment plant that provides recycled water for irrigation use. Additional sampling events should also be scheduled following any change in the treatment process. During this study, constituent concentrations in recycled water were observed to vary within the distribution system. Therefore, it is recommended that samples be collected at various points in the distribution system to evaluate the quality of recycled water being applied for irrigation. Samples should be collected at the irrigation site closest to the recycled water source, and at the irrigation site furthest from the recycled water source. Additional samples within the distribution system may be warranted based on size of the distribution system. Note that as the recycled water distribution systems are expanded, sampling locations may need to be revised or added over time.

A list of the constituents to be analyzed for future monitoring is presented in Table V-4-1. The list contains constituents of recycled water that were determined by this study to be of concern with regard to adverse impacts to groundwater. The list of constituents may be revised if it is suitably demonstrated that one or more of the constituents is consistently below detection in the recycled water source. The constituent should be below detection in all samples collected from the distribution system. All constituents should continue to be monitored in the recycled water source. In addition, this list of constituents may be adapted in the future to include new contaminants in recycled water that are identified and determined to have merit for monitoring.

The monitoring approach, including constituents monitored and monitoring frequency, may be revised as more site-specific data becomes available. To date, there is limited field-scale data on long-term impacts to groundwater from recycled water application, particularly for some of the constituents of concern. With additional data from further studies, revisions to this monitoring approach should be evaluated with consideration of the applicability of the new data to recycled water application within the study area.

VOLUME V
PROPOSED RECYCLED WATER IRRIGATION SCREENING LEVELS, BEST MANAGEMENT PRACTICES, AND ONGOING MONITORING RECOMMENDATIONS

1. INTRODUCTION

This report was prepared by Locus Technologies (Locus) on behalf of the Santa Clara Valley Water District (SCVWD) for the Recycled Water Irrigation and Groundwater Study. Volume V of this report covers proposed recycled water irrigation screening levels (PRWISLs), best management practices (BMPs), and ongoing monitoring recommendations. This volume focuses on the last phase of this study which is guidance for use of recycled water in irrigation in the study area in a manner that sustainably protects groundwater from this particular use. Protecting groundwater means ensuring that negative impacts of recycled water for irrigation in groundwater are minimized.

1.1. Purpose

This volume of the report includes proposed recycled water irrigation screening levels (PRWISLs), best management practices (BMPs), and ongoing monitoring recommendations. PRWISLs are maximum tolerable concentrations of recycled water constituents in irrigation water. BMPs are effective and practical methods for using recycled water in irrigation that aim to protect to groundwater quality. These BMPs were developed with two major considerations in mind: 1) to protect groundwater resources and 2) to maintain recycled water as a viable source for irrigation. Ongoing monitoring recommendations are established to maintain proposed recycled water irrigation screening levels in the irrigation water and preemptively identify potential effects to groundwater. Together, RSWLs, BMPs, and ongoing monitoring recommendations aim to minimize groundwater degradation from recycled water irrigation. The following goals were identified for Volume V:

- Define proposed recycled water irrigation screening levels for recycled water constituents.
- Establish best management practices for sustainable use of recycled water as an irrigation source with regard to protection of groundwater.
- Specify ongoing monitoring provisions to track irrigated recycled water and groundwater at implemented areas.

2. DEVELOPMENT OF PROPOSED RECYCLED WATER IRRIGATION SCREENING LEVELS

Proposed recycled water irrigation screening levels (PRWISLs) were developed for irrigation to protect groundwater sources in the study area, in conjunction with BMPs and ongoing monitoring recommendations. For this study, the PRWISL is defined as the maximum concentration of a recycled water constituent present in irrigation water at which minimal groundwater degradation potential can be achieved. Recycled water concentrations higher than the PRWISLs will always result in greater than minimal groundwater degradation potential. However, a recycled water quality that meets all the PRWISLs does not necessarily indicate minimal groundwater degradation potential because the PRWISL of each constituent assumes there is no contribution to the GWDP from the other constituents. To quantify the GWDP, the forward evaluation for determining the groundwater degradation potential as discussed in Volume IV must be performed. Recalculation of the GWDP is useful whenever there are changes in the recycled water quality..

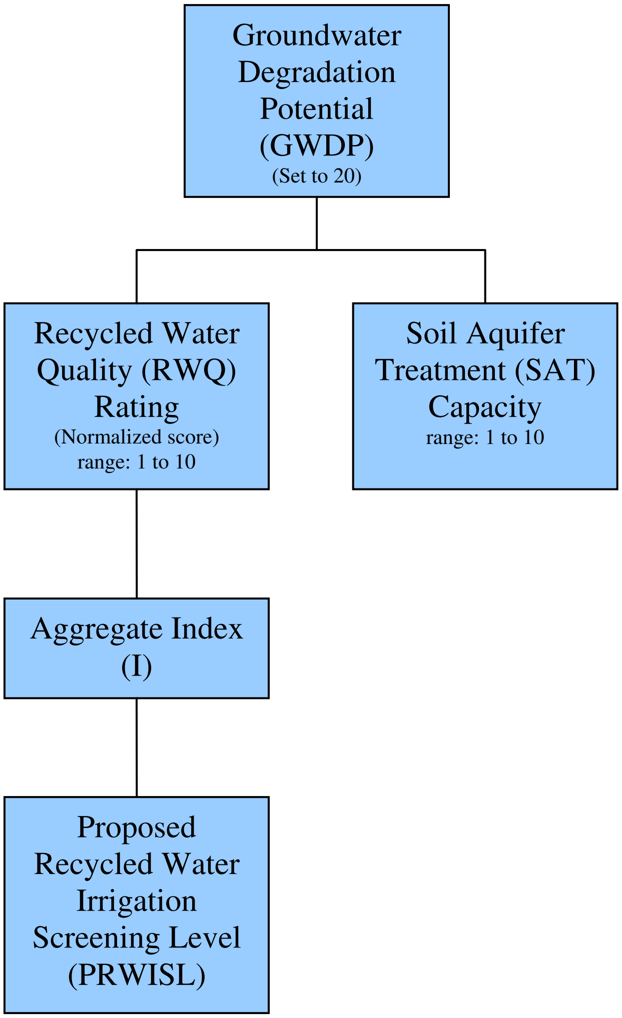
The PRWISLs vary within the study area based on the soil aquifer treatment capacity of a given area and the representative groundwater quality. The PRWISLs also consider the constituent's threat level as determined in Volume III of this study. The PRWISL of a given constituent is determined by assuming that the other recycled water constituent concentrations are equal to or less than the representative groundwater quality. The PRWISL of a single constituent represents the maximum tolerable concentration at which the target groundwater degradation potential can no longer be achieved regardless of the other constituent concentrations. PRWISLs are advisory levels based on the findings from this study. The PRWISLs may need to be refined as future studies contribute to the current understanding of recycled water fate and transport.

Proposed recycled water irrigation screening levels are shown in Table V-2-1 and are established for each soil aquifer treatment zone. For compatibility in determining a PRWISL with the method for determining groundwater degradation potential (Volume IV), only constituents evaluated in the groundwater degradation potential methodology were included in this evaluation. Constituents excluded from PRWISL evaluation include alkalinity, dissolved oxygen, oxidation reduction potential, chlorine, pH, total dissolved solids, and heterotrophic plate count. The rationale for exclusion of these constituents is documented in Volume IV of this study. In addition, a PRWISL was not developed for Sodium Adsorption Ratio (SAR) because the effect of SAR is not correlated to the SAT zones as the other constituents are.

2.1. Methodology

To determine proposed recycled water irrigation screening levels, an inverse calculation approach was used from the methodology developed for determining the groundwater degradation potential (Volume IV). An inverse calculation refers to setting the value of the result to determine the value of the input. The groundwater degradation potential describes the potential for groundwater quality to be impacted by recycled water used in irrigation. The groundwater degradation potential (GWDP) is based on (1) the hydrogeological characteristics (SAT capacity) and (2) the quality of the recycled water applied for a given area. A full description of the calculation methodology for SAT capacity and groundwater degradation potential is found in Volume IV of this report.

By constraining the groundwater degradation potential to a maximum target acceptable level that protects groundwater from negative impacts, an inverse analysis can be performed to compute proposed recycled water irrigation screening levels that meet the given criteria. Below is a flow chart of variables used in determining the proposed recycled water irrigation screening levels.



Groundwater Degradation Potential (GWDP)
(Set to 20)
Recycled Water Quality (RWQ) Rating
(Normalized score)
range: 1 to 10
Soil Aquifer Treatment (SAT) Capacity
range: 1 to 10
Aggregate Index (I)
Proposed Recycled Water Irrigation Screening Level (PRWISL)

2.1.1. Groundwater Degradation Potential

Groundwater degradation potential is defined as the potential for groundwater to be impacted by recycled water used in irrigation. The full calculation method for GWDP was described in Volume IV of this study. The GWDP rating system ranges from 0 to 100 with a higher rating referring to a greater threat potential. For this inverse evaluation, the groundwater degradation potential was constrained to a target rating of 20. A rating of 20 is defined for areas with recycled water that has relatively low potential to degrade groundwater. For reference, the GWDP at the pilot study site was found to be 24 using site-specific data.

2.1.2. Soil Aquifer Treatment Capacity

Soil Aquifer Treatment (SAT) capacity is defined as the ability of the soil and aquifer to naturally treat recycled water contaminants. SAT capacity values for the entire study area were developed in Volume IV of this study, based on hydrogeological characteristics including the depth to groundwater, type of shallow soil media, and the type of vadose zone media. SAT capacity values ranged from 1 to 10 within the study area. Low SAT capacity values indicate areas of relatively protective conditions for groundwater. High SAT capacity values indicate areas where groundwater is more vulnerable to contamination from recycled water irrigation.

Because the SAT capacity varies within the study area, the PRWISLs were calculated separately for multiple values of SAT capacity. The SAT capacity range of 1 to 10 was divided into five categories as shown in Table V-2-1.

2.1.3. Recycled Water Quality Rating and Aggregate Index

In Volume IV of this study, recycled water quality (RWQ) ratings were calculated as an overall index of the quality of recycled water sources, considering the concentrations of various constituents that could threaten groundwater. The RWQ rating system ranges from 1 to 10, with higher values indicating higher constituent concentrations. The GWDP was calculated for each area by multiplying the SAT capacity rating with the RWQ rating. For the inverse calculation, the maximum acceptable RWQ rating is determined by the following equation

$$[\text{RWQ rating}] = \frac{[\text{GWDP rating}]}{[\text{SAT rating}]}$$

[RWQ rating] = maximum acceptable recycled water quality rating.

[GWDP rating] = groundwater degradation potential rating, which is set to the target threshold of 20 for this evaluation (Section 2.1.1).

[SAT rating] = soil aquifer treatment capacity rating which ranges from 1 to 10 (Section 2.1.2).

Because the SAT rating varies within the study area, the RWQ rating is calculated separately for each SAT rating category. For each category, the more conservative (i.e. greater) value of SAT capacity was used to calculate the RWQ rating. Using this approach, maximum acceptable recycled water quality ratings are calculated for each zones of soil aquifer treatment capacity as shown in Table V-2-1.

As described in Volume IV, the RWQ ratings were calculated from the aggregate index (I) values using:

$$[\text{unscaled RWQ rating}] = 1 - \mathrm{I}$$

The unscaled RWQ ratings were then rescaled to a range of 1 to 10, based on groundwater concentrations (RWQ rating = 1) and maximum recycled water concentrations (RWQ rating = 10). To back calculate the aggregate index from the maximum acceptable RWQ rating for this evaluation, the RWQ ratings were rescaled from zero to one using the same values. Then the aggregate index was calculated from the RWQ rating using the above equation.

2.1.4. Subindices, Groundwater Quality, and Subindex Exponent

As described in Volume IV, the aggregate index, I, was calculated using the following equations:

$$\mathrm{I} = \left(1 - \mathrm{N} + \sum_{i=1}^{\mathrm{N}} s_i^{-1/k}\right)^{-k} \text{ such that } k = \frac{1}{\log_2(\mathrm{N}-1)} \text{ and } s_i = \left(1 + \frac{q_i}{q_{ci}}\right)^{-m}$$

Where

I = Aggregate index of the recycled water quality.
N = Number of subindices considered. In this study, the number of subindices corresponds to the number of constituents evaluated (N=37).
s_i = Subindex for the individual constituent i.
q_i = Quality of constituent i, which is taken to be the difference between the constituent concentration in recycled water and q_{ci}. q_i is set to zero if the recycled water concentration is lower than q_{ci}.
q_{ci} = Representative groundwater quality for constituent i, which is the current groundwater concentration of the given subbasin with 20 percent of the available assimilative capacity.
m = Subindex exponent. In Volume IV, the following equation was used:
m = [Threat] × ([Threat] – 1) × [mscale]
[mscale] = 0.020783 as determined in Volume IV.

[Threat] = Threat assigned to given constituent as determined in Volume III. Values range from 1 to 5.

The PRWISL for each constituent is the maximum concentration that results in the target groundwater degradation potential. To calculate that value, the specific constituent being evaluated would be the only constituent that contributes to groundwater degradation potential. All other constituent concentrations would be less than or equal to groundwater concentrations plus 20% assimilative capacity. For those constituents, the value of q is zero, and the subindex (s) value for those constituents would be 1. Using the constant value of N=37, and the assumption that 36 of the constituent subindex values are 1, the above equation reduces to I = s.

Using the subindex equation to solve for the constituent quality (q) yields:

$$q_i = \left(I^{-1/m} - 1\right) \times q_{ci}$$

This equation is used to calculate constituent quality values based on the aggregate index I (Section 2.1.3), the subindex exponent m (calculated using the constituent threat as shown above and in Volume IV), and the representative groundwater quality q_{ci}. Values of q_{ci} were determined for each constituent in each groundwater subbasin in Volume IV. Since the values of q_{ci} are different for each subbasin, the PRWISLs are calculated separately for each subbasin.

2.1.5. Proposed Recycled Water Irrigation Screening Level

The constituent quality (q_i) can be expressed as q_i = PRWISL - q_{ci}. Therefore the PRWISL for constituent i can be calculated as follows:

$$\mathrm{PRWISL}_i = \left(I^{-1/m} - 1\right) \times q_{ci} + q_{ci}$$

Using values of m and q_{ci} from Volume IV, and the aggregate index calculated for each SAT capacity, the calculated PRWISLs are shown in Table V-2-1. Direct use of the results of this equation can yield PRWISLs that are higher than maximum concentrations observed in recycled water. Where the calculated PRWISL is greater than the maximum observed concentration in recycled water, the maximum observed concentration is substituted as the PRWISL. This substitution was implemented because concentrations higher than current recycled water maximum values could not be evaluated in this study. Therefore, the PRWISLs must be set so that recycled water quality is either maintained or improved and is not allowed to decline.

2.2. Assumptions

Proposed recycled water irrigation screening levels are set such that the PRWISL of a given constituent will result in the target groundwater degradation potential (GWDP) of 20. This assumes that the quality of recycled water with respect to all other constituents will be at or below representative groundwater quality. As a result, a theoretical recycled water source with concentrations below the PRWISLs for the given SAT zone may still exceed the target GWDP, since the GWDP is calculated based on the aggregated quality of all constituents. PRWISLs were developed in this manner because there is no unique set of concentrations that would result in the target GWDP. To properly evaluate the GWDP for a given water chemistry, the forward calculation as described in Volume IV must be implemented. The PRWISLs are more appropriate for definitively determining when a recycled water source would have greater than minimal GWDP.

The PRWISLs assume that recycled water is the only source of pollution. Areas with other contamination sources in the surface or subsurface pose additional risk groundwater contamination due to mobilization of irrigation water. The irrigation water acts as a major vehicle for mobilizing constituents towards groundwater. It is recommended that application of recycled water is avoided in these areas, as discussed in Section 3.3.

2.3. Limitations

The development of the PRWISLs is subject to the same limitations as the determination of groundwater degradation potential, discussed in Volume IV. The threat values for this study were determined for each recycled water constituent based on available data from the bench test and pilot study. Additional long-term monitoring within the study area may reveal that some constituents are more or less of a threat compared to what was concluded from those investigations. Revisions to the threat levels would directly affect the PRWISLs.

The focus of the PRWISLs is to minimize groundwater degradation caused by recycled water irrigation. Separate consideration is needed for other factors that may limit the allowable concentration of recycled water. An example is salt tolerances of crops that may require more stringent recycled water levels.

Salt tolerances can limit the allowable quality of recycled water. Salts accumulate at the root zone as water is lost through transpiration of plants and evaporation. Plants that are exposed to more salt, expend greater energy to draw water from the soil. Tolerances vary by crop. *Salt Management Guide for Landscape Irrigation with Recycled Water in Coastal Southern California* (Tanji, et. al, date unspecified) provides data on salt thresholds for specific plant species. Winter precipitation and over-irrigating can contribute to the flushing of salts, which can be a concern for groundwater quality.

3. BEST MANAGEMENT PRACTICES

The best management practices (BMPs) presented in this section are recommendations to maintain optimal use of recycled water for irrigation while protecting groundwater. These BMPs are specific to recycled water use as an irrigation source for landscape, and are evaluated with respect to their potential impacts on groundwater resources. Because the main focus of this study is protection of groundwater, BMPs for recycled water use with regard to public health and safety, such as signage, are not discussed in this report unless they also have an impact on potential degradation of groundwater. A comprehensive overview of current BMPs for landscape irrigation can be found in publications such as *Turf & Landscape Best Management Practices* developed by the Irrigation Association (Irrigation Association, 2005). The document includes provisions for an irrigation system's overall quality, design, installation, maintenance, and management.

3.1. Improve Recycled Water Quality

Dilution of recycled water with higher quality water reduces the concentrations of residual contaminants found in recycled water. With dilution, recycled water can be made acceptable for use in areas that otherwise have too high of an acceptable groundwater degradation potential. Expanding the use of recycled water to these areas helps maximize the value of this resource. Areas where dilution should be implemented will vary by the quality of the recycled water source and the area's soil aquifer treatment capacity. Due to costs associated with implementing dilution (i.e. construction of an onsite holding tank), dilution is most practical for sites with large areas of landscaping. Title 22 prohibits any physical connection between recycled water systems and potable water systems without specific backflow protection devices.

Dilution may be an appropriate measure for areas where the constituent concentration of concern in the recycled water is above PRWISLs established for recycled water. PRWISLs, found in Chapter 2 of this document, specify threshold concentrations in recycled water that may achieve the target groundwater degradation potential. PRWISLs are specific to the soil aquifer treatment capacity for the area. Areas with differing soil aquifer treatment capacity have a different set of PRWISLs. Where the recycled water constituent concentration is above PRWISLs, dilution should be considered.

Dilution needs may change as the concentration of a constituent in recycled water may change over time. Periodically reevaluating dilution needs will ensure PRWISLs are met. If the concentration of a constituent in recycled water fluctuates in a given range, the upper value of that range should be used for dilution calculations. A higher concentration in recycled water will yield a greater dilution requirement. The monitoring recommendations in Section 4.2 would be sufficient for determining the appropriate amount of dilution.

In addition to dilution, source control (i.e. controlling the water quality at the treatment plant) may be an option for reducing the concentration of residual constituents of concern found in recycled water. Source control options could involve modifications to treatment processes that will improve the removal of the residual constituents. Source control could also include identification and elimination of sources of recycled water constituents from the waste stream used as the source for recycled water.

3.2. Fertilizer Use

Because nutrients such as nitrogen, phosphorus, and potassium found in fertilizer are also found in recycled water, the need for fertilizer in landscape management can be reduced. Nutrients found in recycled water are significant enough in quantity to supplement fertilizer application. Reducing fertilizer use is of particular importance with regard to nitrate, which is a major groundwater pollutant in a portion of the study area (SCVWD, 2010).

Balancing the overall load of nutrients onto irrigated landscape reduces excess nutrients that are not removed by the root uptake pathway. Over-fertilization in addition to recycled water use can exceed the root uptake as a sink for nutrients. Nutrients that are not taken up by plant needs can travel past the root zone and potentially reach groundwater.

Reducing fertilizer use is applicable for any site using recycled water for irrigation. Recycled water within the study area is currently obtained from one of four sources: Palo Alto Regional Water Quality Control Plant (PARWQCP), South County Regional Wastewater Authority (SCRWA), San Jose / Santa Clara Water Pollution Control Plant (SJ/SC WPCP), and Sunnyvale Water Pollution Control Plant (SWPCP). All of these recycled water sources contains concentrations of nutrients. Mean concentrations of nitrate from the four recycled water sources range from 10 to 104 mg/L as NO_3. Table IV-3-2 from Volume IV contains average concentrations of constituents, including nutrients, of each recycled water source.

To determine how much fertilizer is needed, the landscape manager needs to determine the annual quantity of nutrients needed for the landscape, the annual volume of the recycled water applied to the site, and the concentrations of nutrients found in the recycled water. The nutrient content of fertilizer is typically identified using three numbers representing the percentages by weight of nitrogen, phosphorus, and potassium. For example, a fertilizer labeled 21-7-14 contains 21% nitrogen, 7% phosphorus, and 14% potassium.

The following mass balance equation can be applied to determine the fertilizer needs for a given nutrient with application of recycled water.

$$[\text{Fertilizer need}] = [\text{Landscape requirement}] - 6.24 \times 10^{-2} \left(\frac{[\text{Vol. of RW}] \times [\text{Conc. in RW}]}{[\text{Area}]} \right)$$

Fertilizer need =	Annual amount of nutrient in the form of fertilizer needed for landscape (lb/1000 sq ft-yr)
Landscape requirement =	Annual amount of nutrient needed including uptake efficiency for the landscape based on type of plant (lb/1000 sq ft-yr)
6.24×10^{-2} =	Conversion factor from [mg-ft/yr-L] to [lb/1000 sq ft-yr]
Vol. of RW =	Annual volume of recycled water applied to landscape (acre-ft/yr)
Conc. in RW =	Average concentration of the given nutrient in recycled water source (mg/L)
Area =	Area of the irrigated landscape (acre)

Example:

Assume that the landscape manager at the pilot study site, by trial and error, determined that the nitrogen requirement for the given landscape is 1.8 lb of N / 1000 sq ft per year. Volume application of recycled water at the pilot study was 8,717 ccf/yr (20.0 acre-ft/yr) and the recycled water concentration of nitrate was 10.6 mg/L as N. The area of irrigation for the pilot study was 6.2 acres. The contribution of nitrogen from recycled water is 2.13 lb of N / 1000 sq ft per year. The difference is an excess of 0.33 lb of N / 1000 sq ft needed for fertilizer. This means that recycled water in this example can supply 118% of the nitrogen needs for the landscape. For this scenario, application of nitrate-containing fertilizer should be minimized or avoided.

Any changes with respect to landscaping requirements or recycled water applied will change the fertilizer needs. Landscaping requirements may change when the type of vegetation is replaced. Different landscape types may also have different fertilizer needs depending on the season. Change in the volume of recycled water applied per unit area or quality of recycled water can also change the fertilizer need. When such changes occur, reevaluate for the appropriate fertilizer need.

3.3. Site Selection

In considering areas for recycled water use, this study recommends screening sites for potential sources of pollution. Areas with other contamination sources in the surface or subsurface pose additional risk of groundwater contamination due to mobilization from the irrigation water. The irrigation water acts as a major vehicle for mobilizing constituents towards groundwater, which is true for any irrigation source. For example, known contamination sites that are undergoing soil and/or groundwater remediation would not be a candidate for irrigation with recycled water. Sites that are free of contamination issues avoid the potential for mobilizing contaminants that are already present at the site.

When considering potential expansion areas for recycled water irrigation, the soil aquifer treatment capacity can be used to indicate which locations are more protective of groundwater. Values of soil aquifer treatment capacity were determined in Volume IV for the entire study area, and are shown in Figures IV-2-11 and IV-2-12. Recycled water irrigation is less likely to impact groundwater in areas of high or good soil aquifer treatment capacity. Areas with marginal or least capacity should be evaluated carefully before recycled water irrigation is implemented.

In addition, sites need to be screened for proximity to nearby water supply wells. As established in Title 22, irrigation using recycled water should not take place within 50 feet of any domestic water supply well, unless the well owner specifically allows recycled water application within 50 feet, and a number of physical requirements for the well are met.

Sites should also be screened for vertical conduits (such as abandoned or improperly sealed wells) which may accelerate the mobilization of contaminants downward. Vertical conduits may be addressed by avoiding such sites or sealing the conduits prior to recycled water implementation. Evaluating the site stratigraphy may be useful for determining the potential for lateral movement of water. Where there is significant lateral movement of water consider also checking for vertical conduits around the site nearby.

3.3.1. Potential Contamination Sources

Potential contamination sources from the land surface include land disposal sites, stockpiles, disposal of sewage and water treatment plant sludge, heavy use of fertilizers and pesticides, accidental spills of hazardous materials, and particulate matter from airborne sources. Potential subsurface contamination sources above the water table include leaching septic systems, holding ponds, sanitary landfills, waste disposal in excavations, leakage from underground storage tanks or pipelines, sumps, drywells, and cemeteries.

3.3.2. Screening Method

If a potential area of expansion is not well characterized enough to make a decision on site selection, consider using tools from an environmental assessment of the area of interest. EPA's "All Appropriate Inquiries" (AAI) rule provides useful guidance on evaluating a property's environmental conditions and assessing potential liability for any contamination. Two American Society for Testing and Material (ASTM) standards are compliant to the AAI rule. These include ASTM International's E1527-05 "Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process" and ASTM E2247-08 “Standard Practice for Environmental Site Assessments: Phase I Environmental Site Assessment Process for Forestland and Rural Property.” Important elements in screening for appropriate sites include:

- Interviews with past and present owners, operators and occupants;
- Review of historical sources of information;
- Review of federal, state, tribal, and local government records;
- Visual inspection of the facility and adjoining properties;
- Commonly known or reasonably ascertainable information;
- Degree of obviousness of the presence or likely presence of contamination at the property and the ability to detect the contamination.

3.4. Irrigation Effectiveness

The focus of this study is potential groundwater impacts resulting from use of recycled water for irrigation. BMPs that address the irrigation systems have a direct impact on the distribution of recycled water constituents at the surface, and thus the potential impact to groundwater. Optimizing the efficiency of an irrigation system minimizes the total volume of irrigation needed for application and consequently minimizes the mass loading of recycled water constituents to the site. An optimized irrigation system distributes water uniformly on the landscape, saving money from overwatering, and reducing ponding and surface runoff.

Irrigation using recycled water should be applied such that the infiltration of water past the active root zone is minimized. The volume of water past the root zone contributes to the advective transport of constituents to groundwater. Reducing the volume past the root active zone limits the advective migration of recycled water constituents towards groundwater while irrigation is being applied, although constituents are still flushed downward during precipitation events. Some water infiltration past the root zone is needed to remove salts from the root zone. Ideal irrigation systems should apply no more water than is needed to combat salt buildup. The amount of water needed to remove the excess salts from soils is known as the leaching requirement, which is generally 10 to 30 percent more than the landscaping water requirement.

3.4.1. Appropriate Irrigation Needs

Irrigation needs can be determined using the Landscape Coefficient Method which estimates irrigation needs of landscape plantings in California by using crop coefficients and reference evapotranspiration values. The landscape coefficient method is described in "A Guide to Estimating Irrigation Water Needs of Landscape Plantings in California" (University of California Cooperative Extension, California Department of Water Resources, 2000). It is critical that the determination of the water budget is done accurately so water needs of the crop are met without over-application.

Irrigation should be adjusted accordingly with weather patterns. Irrigation should not fully saturate the soil. Deficit irrigation techniques that leave room in the root zone for additional moisture from rainfall have been demonstrated to protect groundwater without yield reductions (Food and Agriculture Organization of the United Nations, 2002). To prevent deep percolation below roots and runoff, application should not exceed the infiltration rate of the soil or plant needs, except as needed for flushing salts. For salt management, Oster (SCVWD et al, date unspecified) recommends ceasing irrigation with recycled water once two inches of rainfall have occurred during the winter season, restarting irrigation in late spring. However, this recommendation is specific to redwood trees, and may not be appropriate for all landscape types. Seasonal reductions in recycled water application would reduce the annual mass loading of recycled water constituents and therefore reduce the potential impact to groundwater.

Landscape managers can also assess the characteristics of a site through a water audit every three years by a certified irrigation auditor, such as the SCVWD's current Landscape Survey Program (LSP). The SCVWD's LSP includes an in-depth evaluation of the entire water delivery system and points out inefficiencies that can add up to significant water losses. It also includes calculation of an optimum water budget and recommendations for improving system efficiency including upgrading irrigation hardware as well as providing a suggested yearly watering schedule.

3.4.2. Efficient Irrigation System

An efficient irrigation system can help protect groundwater by reducing the over-irrigation of recycled water and consequently the overall mass load of recycled water constituents at the site. The efficiency of an irrigation system can be improved through design, installation, and regular maintenance of the system. Several resources are available to improve an irrigation system. The California Department of Water Resources Model Water Efficient Landscape Ordinance (California Department of Water Resources, 2009) provides guidance on efficient irrigations systems. In addition, the Eastern Municipal Water District from Riverside County authored *"Recycled Water Use Guidelines and Best Management Practices"* (EMWD, date unspecified) which contains tips to improve the irrigation system. The Olivenhain Municipal Water District also maintains a "*Recycled Water Use Guidelines and Best Management Practices*" document (Olivenhain Municipal Water District, date unspecified) with similar content.

3.4.3. Time of Operation

The evening and early morning are typically recommended as optimal times to apply irrigation for two reasons: 1) there is less evaporation loss during this time and 2) there is less human exposure to recycled water due to lower foot traffic during this time. The disadvantage to early morning and late evening irrigation is a lack of potential photodegradation of light-sensitive constituents, such as n-nitrosodimethylamine (NDMA), which has been found to degrade in UV light. However, previous studies have shown that there is little difference in NDMA fate and transport between daytime and nighttime irrigation schedules (Gan et al, 2006). Therefore, due to the limited apparent benefit of photodegradation and potential health concerns associated with direct exposure to recycled water, irrigation during daylight hours is not recommended unless human contact with the irrigation water can be prevented.

3.5. Salt and Nutrient Management Plan

A salt and nutrient management plan should be prepared in accordance with the State Water Resources Control Board (SWRCB) Recycled Water Policy (SWRCB, 2009). The purpose of a salt and nutrient management plan is to protect groundwater from accumulating concentrations of salts and nutrients from recycled water and other sources that would degrade the quality of groundwater and limit its beneficial uses. The plans are tailored to address the water quality concerns in each groundwater basin or subbasin. The plans may also include constituents that impact water quality other than salts and nutrients. The SWRCB has also specified required elements for a salt and nutrient nanagement plan, including a basinwide monitoring plan, water recycling goals and objectives, salt and nutrient source identification, and implementation measures to manage the salt and nutrient loading. The plan should also include estimates for assimilative capacity, which was discussed in Volume IV of this report. The SWRCB recycled water policy states that salt and nutrient management plans should be completed and submitted to the appropriate Regional Water Resources Control Board (RWQCB) by 2014. The SCVWD is working to develop salt and nutrient management plans for the Santa Clara and Llagas Subbasins in coordination with basin stakeholders.

3.6. Gypsum Use

The use of gypsum greatly increases the percolation of water through clayey soils, improving infiltration and accessibility of water to plant roots. In Volume II of this study, gypsum was found to be very effective in increasing the hydraulic conductivity of soils within the study area. Good soil drainage is important to prevent water-logged soil and in turn promote healthy vegetation. However, with recycled water, increasing permeability also decreases the attenuation capacity of the soil due to less residence time for attenuation of recycled water constituents. Hence, mobility of constituents found in recycled water is increased when gypsum is applied.

In practice, gypsum is used in areas with clayey soils which have low permeability. An appropriate level of gypsum is best determined by trial and error such that sufficient infiltration is reached for the amount of water needed by the crop.

From a groundwater protection standpoint, gypsum should be used in moderation with recycled water. However, it should be noted under-application of gypsum can result in poor infiltration and possible ponding and/or runoff. Runoff of recycled water to surface water bodies is prohibited.

Oster (SCVWD et al, date unspecified) recommends gypsum application before the rain season begins because 1) it will prevent low soil salinities developing at the soil surface as a result of leaching by rain, 2) it will reduce sodium levels in the soil near the soil surface, and 3) salinity effects on plants are minimized during the winter due to low temperatures and high humidity. The effect of gypsum is most pronounced immediately after application. Hence, this recommended application schedule also has the benefit of increasing the infiltration rate most when recycled water application is expected to be lowest. With a properly operated irrigation system, the amount of applied recycled water should be reduced during the rain season.

4. ONGOING MONITORING RECOMMENDATIONS

Recommendations for ongoing monitoring were developed to evaluate the potential long term impacts to groundwater from use of recycled water for irrigation in the Santa Clara and Llagas Subbasins. The goal of the ongoing monitoring is to verify over the long term that the groundwater degradation is minimized as a result of recycled water use.

This chapter discusses constituents to analyze, sources to monitor, and frequency of sampling for an ongoing monitoring program. Monitoring recommendations also apply to further monitoring at the pilot study site. These monitoring recommendations serve as a general guideline for monitoring activities, based on the information compiled for this study. Future modifications of this monitoring schedule may be appropriate to optimize this program.

The approach used to develop these monitoring recommendations has similarities to the approach developed and used in *Monitoring Strategies for Chemicals of Emerging Concern (CECs) in Recycled Water* (SWRCB, 2010) including prioritization of constituents using concentrations in recycled water compared to a baseline value. However, the monitoring recommendations in this report are not limited to emerging contaminants, and the basis for selection of constituents is the groundwater degradation potential which is determined in the Volume IV of this report. The basis of selection from the SWRCB document was toxicological relevance. In the SWRCB document, the focus was on three reuse practices 1) indirect potable reuse via surface spreading of recycled water; 2) indirect potable reuse via subsurface injection of recycled water into a potable aquifer; and 3) urban landscape irrigation with recycled water. This report focuses only on the third reuse practice and uses constituent transport evaluations to guide these monitoring recommendations. The SWRCB used only toxicological information in guiding monitoring strategies.

.

4.1. Groundwater Monitoring

Monitoring the quality of groundwater over time ensures that groundwater quality is maintained for the present and future. Ongoing monitoring allows for appropriate use of recycled water with respect to groundwater, and alerts if adjustments are needed in volume or in quality to the recycled water and the irrigation system. Collected groundwater monitoring data should be compared to baseline groundwater samples collected before recycled water irrigation begins, such as the current groundwater quality data presented in Volume IV.

4.1.1. Locations

Groundwater monitoring should target areas where recycled water for irrigation is currently being implemented, or is expected to be implemented. Wherever possible, existing wells should be used as opposed to installing new wells, as a cost-saving measure. Selected wells should target areas that have higher groundwater degradation potential, so that the most sensitive areas of the groundwater basins are monitored. The groundwater degradation potential for the study area is shown on Figure IV-3-3 and IV-3-4 in Volume IV of this report.

Site-specific data can be used to directly calculate the groundwater degradation potential to help determine if additional monitoring is needed. The use of this data, along with available groundwater monitoring results from areas with similar physical and recycled water quality characteristics may reduce the need for additional monitoring.

If additional monitoring is needed, monitoring wells should target both the principal aquifer and the shallow aquifer. The principal aquifer should be monitored since that is the primary groundwater source for most wells in the county. Monitoring of aquifers above the principal aquifer would be useful in providing advance indication of the transport of recycled water. Selected monitoring wells should have screen intervals that do not cross into multiple aquifers, to avoid the effects of diluting the representative groundwater. Wells that are screened in multiple aquifers, whether between a shallow and principal aquifer or among multiple aquifers within the principal zone would not be appropriate for this monitoring.

Ideal monitoring wells are located at sites where the irrigation with recycled water is currently implemented or planned for the future. Monitoring wells at or adjacent to such sites is recommended so that degradation of groundwater due to recycled water use can be observed as early as possible. Relative to the irrigation site, monitoring wells should be directly downgradient of the site to monitor for potential recycled water constituents that may reach groundwater. Monitoring well located between application sites and production wells are also useful to serve as early indication of changes in water quality that may affect production. Local water elevation data is useful in determining groundwater flow direction. Existing knowledge of the site soil profile, from historical boring logs, can also be useful in determining if there are any preferential flow patterns at the site. Depth to water and generalized groundwater gradient direction can be provided by the SCVWD if available, upon request. While not every irrigation site needs to be monitored, at least one should be monitored to represent each region of expansion with similar GWDP values. If a region of expansion contains different rating categories of GWDP, consider monitoring an irrigation site in each unique subregion.

The number of monitoring wells will depend on the extent of expanded use of recycled water. The more wells implemented in the monitoring program, the better characterized the transport of recycled water will be and ideally each area of planned expansion would be represented. However, cost considerations will limit the number of wells. Preferably, existing wells should be used where available.

Within the area of current or planned recycled water irrigation, the location of monitoring wells should prioritized to areas of highest groundwater degradation potential as shown on Figures IV-3-3 and IV-3-4 of Volume IV of this report. As mentioned above, direct calculation of the groundwater degradation potential using site-specific data and consideration of available groundwater monitoring results from areas with similar physical and recycled water quality characteristics would help identify areas where additional monitoring is needed.

The following is a summary of proposed criteria for achieving adequate monitoring:

1) Select or install wells at or adjacent to sites where recycled water irrigation is implemented. Monitoring wells should be downgradient of the application area.

2) While not every irrigation site needs to be monitored, at least one should be monitored to represent each region of expansion with similar GWDP values. If a region of expansion contains different rating categories of GWDP, consider monitoring an irrigation site in each unique subregion.

3) Monitoring wells located between application areas and production wells will be useful in monitoring water quality that may affect production.

4) Monitor for the groundwater of interest (i.e. in the principal aquifer) and in shallower aquifers. Shallower aquifers can provide an early indication of changes in water quality.

5) Avoid monitoring wells that are screened in multiple aquifers, since samples would effectively be an average groundwater concentration across multiple aquifers.

6) Use denser monitoring well spacing in areas of higher GWDP where groundwater degradation is most likely to occur.

4.1.2. Frequency

The frequency of groundwater monitoring should be associated with the groundwater degradation potential for each area. Areas with higher groundwater degradation potential merit more frequent monitoring to ensure that groundwater impacts are detected early, and steps can be taken to address those impacts, if warranted. Areas of lower groundwater degradation potential are only likely to show groundwater impacts, if any, over longer time frames.

As a starting point for determination of groundwater monitoring frequency, the results of the pilot study (Volume III) were reviewed. The pilot study site, using site-specific data, has a groundwater degradation potential of 24 on a scale of 1 to 100, which is classified as low potential. The first occurrence of recycled water constituents in groundwater during the pilot study was approximately three months after recycled water implementation, when PFCs were observed in the groundwater. In the pilot study, PFCs were not detected during baseline sampling, and they could be uniquely attributed to the recycled water source. Therefore, three months was established as the reasonable minimum time frame for evaluation of recycled water impacts in areas of low groundwater degradation potential. For a monitoring program, this corresponds to quarterly sampling. Monitoring frequencies for areas with different groundwater degradation potentials should be increased or decreased accordingly.

Since some groundwater degradation was observed in the pilot study under relatively protective conditions, quarterly monitoring is recommended initially as a minimum for all areas to ensure groundwater is protected. Initial monthly monitoring is appropriate for areas of relatively high groundwater degradation potential. Previous phases of the study have shown that over time, groundwater concentrations are expected to become asymptotic as conditions approach long-term steady state. Therefore, it is appropriate to gradually reduce the monitoring frequency over time. Reduced monitoring frequency over time allows for initial confirmation of lack of groundwater degradation, followed by ongoing monitoring at a more appropriate frequency for evaluating long-term conditions.

Below is a recommended schedule of groundwater sampling, with the year indicating the amount of time after recycled water application begins:

Highest Groundwater Degradation Potential in Represented Area	Monitoring Frequency		
	Year 1	Year 2-4	Year 5 and beyond
1-20	Quarterly	Semi-annually in spring and fall	Annually in fall
21-40	Quarterly	Quarterly	Semi-annually in spring and fall
41-60	Monthly	Quarterly	Semi-annually in spring and fall
61-100	Monthly	Quarterly	Quarterly

After a period of monitoring events, if evaluation of the data obtained demonstrates that the quality of groundwater has not degraded past 20 percent of the assimilative capacity and does not show an increasing trend, consideration may be given to reducing the groundwater monitoring scope by decreasing the monitoring frequency or the number of wells monitored. Reduced groundwater monitoring scope should still be within reason to adequately ensure groundwater quality is maintained. Before a reduction in monitoring scope, trend analysis with forward projection of the groundwater concentrations should be used to demonstrate that the concentrations will not exceed 20 percent of the assimilative capacity over a longer time frame. Conversely, if adverse impacts are encountered in a specific area the monitoring scope can be adjusted to increase in frequency or in the number of wells monitored in the specific area.

The long-term monitoring frequencies in the above schedule may be revised with the consideration of additional long-term monitoring data from sites with recycled water irrigation. To date, there is limited field-scale data on long-term impacts to groundwater from recycled water application. With additional data from further studies, revisions to this monitoring frequency should be evaluated with consideration of the applicability of the new data to recycled water application within the study area.

4.2. Recycled Water Sampling

Recycled water monitoring is recommended for treatment plants so that quality of the recycled water is known. If recycled water quality worsens over time, this can have an effect on the groundwater degradation potential, which should be reassessed. Maintaining quality of recycled water ensures safety of groundwater resources.

In addition to recycled water sampling, irrigation water sampling (i.e. sampling of the final product of the water, including any dilution if applicable) is useful in assessing if irrigation water has concentrations exceeding the proposed recycled water irrigation screening levels specified in this report.

4.2.1. Frequency

At minimum, annual monitoring of recycled water is recommended from each wastewater treatment plant that provides recycled water for irrigation use. More frequent monitoring of recycled water may be useful for determining seasonal changes in the water quality, or evaluating water quality changes when improvements in the treatment process are implemented.

4.2.2. Number of Monitoring Points

Constituent concentrations in recycled water may vary within the distribution system. For instance, during the pilot study, PFCs were not detected at the recycled water source, but were detected in water from the irrigation system. Although only one point in the distribution system was monitored for the pilot study, this information is consistent with known fate and transport processes and observations from the bench test, including formation of PFCs from precursors. Concentrations of disinfection byproducts (NDMA, haloacetic acids) were also observed to vary between samples collected directly from the plant and samples collected from the pilot study site. Samples collected at various points in the distribution system may provide further insight on the quality of recycled water over the distribution system. It is not always appropriate to collect recycled water samples only from the treatment plant. Instead, samples should be collected at irrigation sites closest to the recycled water source as well as irrigation sites furthest from the recycled water source. Sampling at those points would have the greatest potential to capture the variability of recycled water chemistry within the study area. Note that as the recycled water distribution systems are expanded, sampling locations may need to be revised or added over time

Any treatment changes or improvement at the water treatment facility can impact the quality of recycled water. Additional monitoring may be needed, in such events, to determine how quality of water may change. If the treatment change results in a reduction in recycled water quality, this may warrant counter measures to meet PRWISLs for recycled water.

4.3. Constituent List

A list of the constituents to be analyzed for future monitoring is found in Table V-4-1. The list contains constituents of recycled water that were determined by this study to be of concern with regard to adverse impacts to groundwater. The constituent list is in accordance with recommendations for further monitoring as discussed in Volume III. This constituent list is recommended for all groundwater and recycled water samples. The reporting limits for all analyses should be at or below the typical reporting limits listed on Table V-4-1.

The list of constituents may be revised if it is demonstrated that one or more of the constituents is consistently below detection, or alternatively below the associated groundwater concentration, in the recycled water source. Three consecutive results below the detection limit or groundwater concentration would be appropriate support for eliminating a constituent from further analysis in groundwater monitoring. However, the constituent must be below detection or groundwater concentration in all samples collected from the distribution system. Some constituents, such as PFCs, may not be detected at the recycled water source, but could be detected further in the distribution system. If monitoring at all points in the distribution system (as recommended in Section 4.2.2) yields concentrations below detection or below the groundwater concentration of a constituent for three consecutive monitoring events, there is sufficient evidence to demonstrate minimal potential for impact of that constituent in the irrigated recycled water. Therefore, the constituent analysis may be eliminated from the sampling program for that recycled water source. If a constituent is eliminated from the sampling program for a specific recycled water source, it may also be eliminated from the groundwater sampling program from the associated area of application. Similarly, the *Monitoring Strategies for Chemicals of Emerging Concern (CECs) in Recycled Water* (SWRCB, 2010), allows for removal of constituents where updated data indicate that the current measured environmental concentrations are less than a “monitoring trigger level”. For this monitoring program, the current groundwater quality is analogous to the “monitoring trigger level”.

The original full constituent list should be applied for recycled water and groundwater samples after any changes in the treatment process that would affect recycled water quality. In addition, this list of constituents may be adapted in the future to include new contaminants in recycled water that are identified and determined to have merit for monitoring.

4.4. Quality Control Samples

Quality control samples such as travel blanks and field duplicates are a valuable part of an overall sampling program to ensure that the sampling program yields analytical results that are representative of the water analyzed and are not biased on the sampling/analysis process or errors from the process. This study recommends collecting and analyzing one set of quality control samples: one travel blank and one field duplicate for every twenty samples, starting in the first year of implementation. Additional types of quality control samples may be warranted if analytical or sampling bias is suspected.

A field duplicate is a duplicate, independent sample collected at the same place, at the same time. The field duplicate and project sample are taken from the same source, stored in separate containers and analyzed independently. It is used to estimate sampling and laboratory analysis precision. Duplicate samples should generally be collected for samples where more constituents are expected to be above the detection limit. For this sampling program, this is expected to be the recycled water source samples.

A travel blank is a sample of analyte-free media, usually deionized water. It is useful to identify errors or cross contamination attributed to shipping and handling procedures.

Notes:

1. For each SAT zone, the most conservative value (ie greater SAT rating) is used for calculating the Recycled Water Quality Rating
2. The maximum possible Recycled Water Quality Rating is 10.
3. The target acceptable Groundwater Degradation Potential is taken to be 20.
4. The derived equation for determing PRWISLs is as follows: PRWISL = (I^(-1/m)-1)*qc+qc
5. Where the PRWISL determined by the equation is greater than the maximum observed in recycled water, the maximum observed value becomes the PRWISL.
6. The PRWISL of a given constituent is developed by assuming that the other recycled water constituents are equal to or less than the representative groundwater quality. The PRWISL represents the maximum tolerable concentration at which the target groundwater degradation potential could still be achieved. However, water quality that is below the PRWISL for each constituent will not neccesarily achieve a groundwater degradation potential below the target level.
